ABSTRACT

Healthy skeletal muscle has a robust ability to respond to tissue damage. Restoration of functional tissue depends on cellular expansion of muscle stem cells, a.k.a. satellite cells (SCs). During resting conditions, healthy muscle fibers have minimal turnover and SCs are mitotically quiescent. However SCs exist in a reversible quiescent state. Tissue damage prompts quiescent SCs to enter the cell cycle to produce progenitors that will differentiate to form new muscle fibers (myofibers) while a portion will self-renew to preserve the stem cell population. The notion that growth factor deprivation during rest is responsible for quiescence led to the widely held belief that quiescence is a passive state. But more recently, researchers have characterized molecules that maintain quiescence by inhibiting proliferation, leading the field to reconsider this notion and recognize maintenance of quiescence as an active state. However the mechanism by which SCs maintain proliferative potential during dormancy has not been studied.

Here, I have identified a CREB-Mpp7-AMOT axis that directs proliferative competence during quiescence. Using a tamoxifen-inducible, Pax7-lineage specific driver to inactivate CREB in SCs, I found that CREB inhibition does not cause a break in quiescence. However, upon muscle damage, SCs without CREB activity showed defective regeneration, attenuated proliferation, accelerated differentiation, and lack of SC self-renewal. Using RNA-seq based transcriptome comparison and ChIP, I determined that *Mpp7* is a CREB target in SCs during quiescence. Using siRNA and

overexpression, I found that Mpp7 is necessary and sufficient to maintain proliferation and self-renewal. Additionally, I found that Mpp7, a scaffolding protein, promotes the polarized localization of AMOT protein and nuclear accumulation of YAP. In summary, I discovered that CREB regulates Mpp7 expression thereby mediating a Mpp7-AMOT protein complex to promote YAP activity upon activation. Lack of CREB activity does not affect quiescence per se, but severely attenuates activation during an injury response. My work delineates a novel protein network that maintains SC activation competence during quiescence for stem cell function.

PREFACE

My research accomplishments and the completion of my degree have been made possible by the invaluable support of the mentors and colleagues around me. I would like to express sincere appreciation for my advisor Dr. Chen-Ming Fan who has provided countless hours of direction through scientific insight, experimental design and critical analysis. Dr. Chen-Ming Fan's valuable advice has enhanced my research and his encouragement has provided me inspiration to pursue my career goals. I would also like to acknowledge my thesis committee, consisting of Drs. Allan Spradling, Trina Schroer, and Yixian Zheng, who have given me an immense amount of quality feedback on my project and helped me to contextualize my work on a broad scale. I would like to thank Drs. Fred Tan and Nicholas Ingolia for assistance designing the analysis strategy for the bioinformatics portion of my work. Previous lab members Drs. Christoph Lepper and Peter Lopez were critical during the initial stages my project by providing training on experimental techniques and engaging in thoughtful discussions of current literature. And current lab member Dr. SiewHui Low has shared her expertise of research concepts and techniques that have allowed me to move past road blocks in my project. Additionally, Dr. Matthew Sieber has provided meaningful guidance as I pursue a career in academia. Lastly, I would like to thank my family and friends for their incredible support.

CHAPTER 1: INTRODUCTION TO MUSCLE STEM CELL MEDIATED REGENERATION

Muscle stem cells

Skeletal muscle enables locomotion of vertebrates. The basic cellular unit of skeletal muscle consists of the myofiber containing the actin-myosin contractile unit that enables force generation. Intimately associated with myofibers are SCs, named such based on the early observation by electron microscopy of their position sandwiched between the basal lamina and cell membrane of the myofibers (Mauro, 1961). Because of their close juxtaposition with the myofiber, SCs were hypothesized to be involved in muscle growth and regeneration (Mauro, 1961). Subsequent experiments using radiolabeled thymidine to trace newly synthesized DNA showed that SCs were proliferative and contributed to newly formed myofibers (Moss and Leblond, 1970, 1971; Reznik, 1969). Culturing isolated myofibers and associated SCs revealed the ability for SCs to migrate away from the myofiber, proliferate, and differentiate fully to form multi-nucleated myofibers (Bischoff, 1975; Konigsberg et al., 1975). Thirty years later, techniques to characterize SCs, such as label retention and transplantation, has been key to showing that SC is a bona fide muscle stem cell *in vivo* (Collins et al., 2005; Shinin et al., 2006).

The functional role of SCs has led to the interest in identifying the molecular properties of these cells. During embryonic myogenesis, a progenitor population arises from the central dermamyotome, expresses Pax3 and Pax7, and are maintained throughout the developing skeletal muscle (Fan and Tessier-Lavigne, 1994; Gros et al., 2005; Relaix et al., 2005). These cells will settle in to the SC position during late fetal development, mirroring their location in the adult muscle (Relaix et al., 2005). Using Pax7 as drivers for conditional expression of reporter constructs, it was shown that these

embryonic precursors do indeed mature into the adult SC (Hutcheson et al., 2009; Keller et al., 2004; Lepper and Fan, 2010). Previously limited to germline mutants, the advent of lineage-specific conditional-activation of Cre by the Cre-loxP system allows for SC specific deletion of genes. This enables the study of gene function of germline lethal genes as well as SC specific manipulations using the canonical biomarker Pax7 to drive specified gene deletions.

Skeletal muscle regeneration

A central property of stem cells is the capacity to generate daughter cells that self-renew and differentiate into specialized cell types (Weissman, 2000). Mammalian stem cells of rapidly regenerating tissues such as the hair follicle, intestinal crypt, and blood are predominantly quiescent while a subset are actively cycling for ongoing tissue restoration (Li and Clevers, 2010). Skeletal muscle, during normal physiology, has low turnover and fittingly, resident muscle stem cells rarely become activated. SCs are normally quiescent (Schultz et al., 1978), however, upon tissue damage, have robust capacity to mount a proliferative program to provide the necessary cellular source for generating new myofibers (Brack and Rando, 2012). In response to injury, damaged myofibers undergo a degenerative phase in coordination with SC activation to replace lost tissue. Proliferating SCs generate mono-nucleated muscle progenitors, termed myoblasts, which undergo fusion to form multi-nucleated myofibers. Myogenic progression of SC derived myoblasts are marked by overlapping but distinct expression of muscle lineage specific genes that designate quiescence: Pax7 (Seale et al., 2000); activation: Myf5 (Davis et al., 1987) and MyoD (Cornelison and Wold, 1997; Davis et

al., 1987); differentiation: Myogenin (Mgn) (Wright et al., 1989) and Mrf4 (Rhodes and Konieczny, 1989); and terminal differentiation: myosin heavy chain (MHC) (Bader et al., 1982). Alterations in the timing and level of expression of these markers indicate an abnormal myogenic program.

In addition to SC derived myogenic lineage, muscle-derived pluripotent stem cells have been suggested to contribute to muscle growth. Bone marrow cells and muscle derived, hematopoietic stem cell marker Sca-1⁺ cells were able to form myocytes and SCs after intramuscular transplantation (Asakura et al., 2002; Gussoni et al., 1999; LaBarge and Blau, 2002). Muscle resident PW1⁺/Pax7⁻ and CD45⁺ interstitial cells have also been shown to contribute to the muscle regeneration *in vivo* (Mitchell et al., 2010; Polesskaya et al., 2003). Similarly mesoangioblasts and pericytes have the capacity to contribute to newly formed myofibers during regeneration (Dellavalle et al., 2007; Sambasivan et al., 2011). Nevertheless, ablation of the SC population results in complete absence of muscle regeneration, providing evidence that SCs are the major contributor to muscle regeneration under the normal physiological conditions (Lepper et al., 2011; Murphy et al., 2011; Sambasivan et al., 2011).

The ability to reform skeletal muscle after damage is of paramount importance to the quality of life. Traumatic injuries, such as heavy weight lifting, mechanical damage and downhill running, engage the SC to proliferate and form new muscle. Disease states such as muscular dystrophy, cachexia, and aging, are accompanied by reduced ability to regenerate due to SC defects. Therefore, the understanding of the basic biology of SCs can inform translational medicine with the goal of restoring muscle growth and function to dystrophic patients.

SC self-renewal

Stem cells are a long-lived population of cells that enable tissue growth throughout the lifetime of animals. SCs have a remarkable capacity to proliferate to form the necessary cells for muscle regeneration. Transplantation of a single myofiber and its associated 7-22 SCs into immunodeficient dystrophic mice generated 100 new multinucleated myofibers, which is equivalent to over 25,000 differentiated myonuclei (Collins et al., 2005). Additionally, the newly formed tissue contained functional SCs that could complete another round of regeneration (Collins et al., 2005). A similar study used single SC transplantations, tracked by luciferase reporter activity, showed that SCs are capable of 14-17 doublings *in vivo* and supplies newly formed myofibers and self-renewed Pax7 expressing SCs (Sacco et al., 2008). These transplantation studies provided key evidence that SCs are able to give rise to differentiate progeny and self-renew.

The mechanism of SC self-renewal has been explored in several studies. SCs are positioned in a polarized environment when they establish quiescence with the apical side juxtaposed to the myofiber and basal side adherent to the basal lamina of the myofiber. Culturing single myofibers and their associated SCs allows for determination of the molecular fates of dividing SCs and their mitotic division plane orientation. SCs showed asymmetric expression of a Myf5 reporter during cell divisions when their division planes were perpendicular to the long axis of the myofiber (Kuang et al., 2008). SC divisions that are oriented parallel to the long axis of the cultured myofiber, planar divisions, are regulated by Wnt signaling and promote symmetric SC expansion (Le

Grand et al., 2009). Interestingly, intravital imaging showed that SCs exclusively contacted the myofiber basement membranes during divisions suggesting that in physiological conditions, only planar divisions occur (Webster et al., 2016). Regardless, the molecular cues from the myofiber are important for self-renewal since Collagen VI, a component of the myofiber niche, is important for SC activation and self-renewal (Urciuolo et al., 2013). All together these studies point to an important role for positional cues coming from tissue architecture to direct SC self-renewal during regeneration.

The molecular components of self-renewal have been explored. A downstream target of RTK signaling, Sprouty1, is enriched during regeneration at the phase corresponding to reestablishment of quiescence and required for restoring the SC pool after injury. Constitutive Notch signaling in SCs promotes the Pax7⁺ fraction while reducing proliferation, thereby representing quiescent SCs in culture conditions (Wen et al., 2012). The polarity protein Mark2 (Par1b) is basally localized in activated SCs and regulates asymmetric division to promote the self-renewing population (Dumont et al., 2015). The cell autonomous molecular properties of SCs have only begun to be explored.

Quiescence and Activation of SCs

SCs show low turnover during normal conditions and are typically quiescent. However reversible quiescence is critical for SCs to both provide cellular supply after injury and to reestablish quiescence when proliferative needs are met. The self-renewed satellite cells form the source of SCs for future rounds of repair. The loss of the ability to maintain a quiescent state, would therefore lead to unrestricted cellular proliferation or the depletion of the SC population due to cellular death or differentiation. The tight regulation of

quiescence and activation are therefore key to the maintenance of SCs throughout the lifetime of the organism.

Quiescence is an active process that requires proper maintenance at the level of transcription, post-transcriptional regulation, and chromatin structure. Suv4-20h1 dependent facultative heterochromatin restricts aberrant MyoD expression and cell cycle entry during quiescence to prevent aberrant activation during homeostasis (Boonsanay et al., 2016). Inhibition of miR-31 by antagomiR tail vein treatment leads to increased Pax7⁺ cells and cell cycle entry which leads to more myonuclei and larger myofibers in the absence of injury (Crist et al., 2012). Calcitonin receptor restricts aberrant cell cycle entry of SCs and prevents emergence from the niche (Yamaguchi et al., 2015). Notch signaling component, RBP-J, prevents aberrant activation and progressive loss of the SC pool due to differentiation during quiescence (Bjornson et al., 2012; Mourikis et al., 2012). These key factors are important during quiescence to restrict the improper activation or differentiation of SCs in the absence of injury.

The maintenance of quiescence is important during the resting phase to preserve the cellular pool. Upon injury, every SC that will give rise to a future SC will undergo at least one round of division (Troy et al., 2012). Therefore, SCs quiescence must be reestablished from a proliferative population during regeneration. Sprouty, which is important for renewing the Pax7 population during regeneration, also is essential for homeostasis of the replenished SC pool after injury (Shea et al., 2010). The forkhead transcription factor FOXO3 promotes self-renewal during regeneration by enhancing Notch-mediate return to quiescent and differentiation inhibition (Gopinath et al., 2014).

Reestablishing the SC population requires the restriction of proliferation and maintenance of an undifferentiated state within a population of transit amplifying myoblasts.

Some of the key factors are important for maintaining quiescence during rest, regaining quiescence after activation, and promoting myoblast expansion are beginning to be revealed. Growth factors are potent promoters of proliferation during regeneration. Insulin-like growth factor (IGF), hepatocyte growth factor (HGF), and fibroblast growth factor (FGF) are released by myofibers and are required to stimulate myogenic proliferation during regeneration (Chakravarthy et al., 2000; Floss et al., 1997; Tatsumi et al., 1998). Interleukin-6 (IL-6) is secreted by myoblasts and macrophages during injury to promote removal of necrotic tissue and synchronize proliferating myoblasts (Cantini et al., 1995). The robust proliferation of myoblasts is mediated by widely expressed growth factors.

While the factors that mediate quiescence and activation have been uncovered, the potential for proliferation during the quiescent state has not been studied. Whether and how a proliferative competent state co-exists with SC quiescence to permit cell cycle entry upon muscle injury is unknown. Based on the rapid response of SCs to stimulus and the repressive role of quiescent factors implies that activation potential is present in the SC. The outstanding question of how SCs are poised to activate yet remain quiescent is investigated in this study.

CHAPTER 2: CREB IS ACTIVATED IN SCS AND MYOGENIC PROGENITORS

INTRODUCTION

CREB mediated transcriptional control

The cAMP-response element binding (CREB) protein family of activators, consisting of CREB, ATF1 and CREM, is important for the execution of various transcriptional programs. The leucine zipper (bZIP) domain and basic region impart selective dimerization and DNA binding, respectively, to all members of CREB transcription factors. CREB regulates transcription of certain genes by binding to conserved promoter elements, cAMP response elements (CRE), as homodimers or heterodimers between CREB family members (Montminy and Bilezikjian, 1987; Short et al., 1986). A dominant-negative inhibitor of CREB, termed A-CREB, was constructed by fusing an acidic extension onto the CREB bZIP dimerization domain. Upon dimerization with A-CREB, CREB proteins are prevented from binding DNA to affect transcription (Ahn et al., 1998). In addition to its DNA binding domain, CREB contains a Ser133 phosphorylation site for PKA, which is stimulated by adenylyl cyclase (AC) via cAMP (Gonzalez and Montminy, 1989). Phospho-Ser-133-CREB interacts with p300/CBP, a histone-acetyltransferase (Bannister and Kouzarides, 1996; Ogryzko et al., 1996) that recruits RNA polymerase II (Nakajima et al., 1997), to promote expression of downstream genes.

CREB signaling in myogenesis and muscle

Previous work by our lab and others has shown that the CREB transcription factor family controls gene expression for proper muscle development, repair, and survival. Our

previous study of CREB function during myogenesis found that adenoviral mediated expression of A-CREB, abolished myogenic gene induction in cultured embryos (Chen et al., 2005). In cultured myoblasts, crushed muscle extracts increased pCREB levels and canonical CREB target gene induction (Stewart et al., 2011). Mice expressing an activation-sensitive form of CREB (CREB-YP) showed increased general cell proliferation after muscle injury (Stewart et al., 2011). Given that CREB activity also prevents muscle fiber death directly and promotes muscle repair indirectly via M2 macrophages (Berdeaux et al., 2007; Ruffell et al., 2009), the general proliferation increase in CREB-YP injured muscle likely has multiple origins. Furthermore, the SCs of CREB-YP mice were not examined nor were regeneration outcomes. As extensive as these collective studies are, the role of CREB activity in adult SCs is unknown.

RESULTS

Differential CREB activity is detected during myogenic progression of SCs

To gain insight into whether CREB activity might operate during adult myogenesis, I conducted a thorough characterization of CREB activity in adult SC and its descendants during myogenic progression by immunofluorescence detection of pCREB. In uninjured tibialis anterior (TA) muscle, pCREB was detected in 97% of SCs (stained positive for the definitive marker Pax7, Pax7⁺; Figure 1), suggesting an active role for CREB during quiescence.

I next examined how pCREB pattern might change after SC activation. For this, I assessed pCREB levels in SCs associated with myofibers at various time points in culture. For identification of SC lineage, we isolated myofibers with YFP marked SCs from tamoxifen (TAM) treated *Pax7^{CE/+};Rosa26^{YFP/YFP}* mice (Figure 2). Immediately upon isolation pCREB was detected in 98% of YFP marked SCs (time 0, T0; Figure 3B), in agreement with *in vivo* pCREB levels of quiescent SCs in uninjured muscles (Figure 1). SCs displayed changed levels of pCREB over 2 days (Figure 3A,B). Using average pCREB fluorescence signal intensity of associated myonuclei as a reference, I observed the SC fraction with high pCREB (>1.5X of myonuclear signal) gradually declined, whereas fractions with low or virtually non-detectable/negative pCREB (1.5-0.5X or <0.5X of myonuclear signal, respectively) increased (Figure 3B).

I also assessed pCREB levels in SC-derived primary myoblasts. Unsynchronized differentiation of this population allowed assessment of pCREB levels in Pax7⁺, MyoD⁺, Mgn⁺, or MHC⁺, each representing a progressively more differentiated state. Pax7⁺ and MyoD⁺ cells were mainly positive for pCREB signal, while only small fractions of Mgn⁺

and MHC⁺ cells had high levels of pCREB (Figure 4A,B). These data extend the prior report showing enhanced pCREB levels in myoblasts after exposure to crush muscle extract (Stewart et al., 2011) by demonstrating that CREB activity is present in quiescent SCs, declines after activation, and is low in differentiating myogenic cells.

DISCUSSION

Characterization of temporal pCREB levels reveals differential CREB activity during quiescence and early activation. Prior observations (Stewart et al., 2011) found that pCREB was present in proliferating myoblasts, however my study of the kinetics of CREB activity during early activation revealed CREB activity during quiescence as well as activated cells. Additionally, I found that pCREB activity was enriched in undifferentiated myoblasts compared to terminally differentiated myoblasts. This could be assessed through co-staining of terminal differentiation markers Mgn and MHC (Figure 3A,B) or by comparing the fluorescence intensity of the SC/myoblast to its neighboring myonuclei. The lack of CREB activity in terminally differentiated myoblasts/myotubes is a bit counterintuitive considering the requirement of CREB activity in maintaining mature myofibers (Berdeaux et al., 2007). However, the study by Berdeaux et al. tested the role of CREB in matured muscle fibers. The study utilized a promoter skeletal muscle actin was used to drive A-CREB in adult myotubes that contain hundreds of myonuclei and have structural requirements that may not be required for newly differentiated cells in culture. In summary these data suggest a novel role for CREB during the quiescent state as well as during early activation.

Figure 1. CREB is activated in quiescent SCs (A) TA muscle sections of 2 month old CD1 wild-type mice. SCs (Pax7⁺) express pCREB⁺. (B) Double positive satellite cells (white arrow) were quantified as a percentage of total Pax7⁺ cells. N=3 mice, n≥50 cells per animal. Data represented as mean +/- 1 standard deviation. Scale bars 10μm

Figure 4. CREB is enriched in Pax7⁺ cells and reduced in differentiated cells (A)

Primary CD1 myoblasts cultured in growth media were assessed for coexpression of pCREB and Pax7, MyoD, Mgn or MHC. Pax7⁺ myoblasts express various pCREB levels. Pax7(low)/pCREB(low) (white asterisk) and Pax7(high)/pCREB(high) myoblasts (red asterisk) were observed. Mgn (green arrow) and MHC (yellow arrow) myoblasts showing absence of pCREB expression. Green and yellow arrowheads indicate Mgn and MHC negative cells, respectively, which serve as as internal positive controls for pCREB expression. (B) Coimmunostaining of pCREB with Pax7 and differentiation markers MyoD, Mgn, MHC show a significant negative association between pCREB versus MyoD, Mgn and MHC expression. n≥150 per marker. ##p<0.01, Chi-squared test. Scale bars 40μm.

METHODS

Mice

Three month old, CD1 wild-type or Pax7^{CE/+}Rosa26^{YFP/YFP} were used. Appropriate mating schemes were performed to obtain Pax7^{CE/+}Rosa26^{YFP/YFP} mice. Animal treatment and care conform to the requirements of the Carnegie Institution and NIH guidelines.

Tibialis anterior (TA) cryosections

Animals were sacrificed by cervical dislocation. TA muscle was immediately dissected and fixed in ice cold 4% paraformaldehyde, EM grade catalog #15710, Electron Microscopy solution, diluted in 1XPBS for 10 minutes. After two washes in ice cold 1XPBS, muscle was subjected to two sucrose treatments, 10% sucrose in PBS and 20% sucrose in PBS for 8-12 hours each. Cryoprotected TA muscle was mounted onto cork slices using tragacanth (1:2::tragacanth:water), catalog # G1128, Sigma. Mounted muscle was submerged in liquid nitrogen cooled isopentane bath for 45 seconds and stored at -80 °C until sectioning. Sections were obtained using Leica cryostat set at -21 °C using 12 µm increments for collecting sections onto Superfrost glass slides, catalog #12-550-15, Fisherbrand.

Single fiber isolation

For immediate fixation, T0 fibers, extensor digitorum longus (EDL) muscles were digested in 0.6% Collagenase, catalog #C0130, Sigma/1XDMEM, catalog #11995-073, Invitrogen, for 15 minutes in 37°C shaking water bath. Using a fire-polished, horse serum coated, wide aperture glass pipette, single fibers were dissociated from EDL muscle by gentle trituration for 10 minutes and fixed for IF.

For single fiber cultures, EDL muscles were digested in 0.2% Collagenase for 1.5 hours and then transferred to 37°C DMEM. Using a fire-polished wide aperture glass pipette, single fibers were dissociated from EDL muscle by gentle trituration for 1-2 hours and transferred to fresh culture media.

Myoblast isolation

Hindlimb muscle was minced and then digested in 0.2% Collagenase for 1.5 hours and then 0.2% Dispase, catalog #17105-041, Invitrogen, (20 mL enzyme solution per mouse) for 20 minutes. Cells were washed twice by spinning and removing cell debris by vacuum aspiration and resuspended in 1XDMEM for washes. Cell pellet was resuspended in 1XDMEM and filtered through 40µm cell strainer and spun. Cell pellet was resuspended in culture media for transfer to matrigel coated (1:100 dilution in DMEM), catalog #356234, BD Biosciences, tissue culture plates.

Tissue culture

Floating myofibers were cultured on horse serum coated 3.5cm tissue culture dishes in plating media (10% horse serum, 0.5% chicken embryo extract, 1XPENSTREP, 1% Glutamax). Myoblasts were cultured on matrigel, (1:100 dilution in DMEM), catalog #356234, BD Biosciences, coated tissue culture plates in, growth media (20% fetal bovine serum, 5% horse serum, 1% chicken embryo extract, PENSTREP, 1% Glutamax, bFGF).

Antibodies

Primary antibodies were mouse IgG1 anti-Pax7 (1:5), DSHB; rabbit anti-pCREB-ser133 (1:1000), catalog # #9198 (87G3); chicken anti-laminin (1:50), catalog #ABIN573807, Antibodiesonline.com, discontinued; chicken anti-GFP (1:250), catalog #GFP1020, Aves

Labs; rabbit anti-MyoD (1:500), catalog #sc304, Santa Cruz; mouse anti-Mgn IgG1 (1:20), catalog #F5D, DSHB, mouse anti-MHC IgG2b (1:20), catalog #MF20, DSHB. Secondary antibodies (all used at 1:500) were goat anti-mouse IgG1, Alexa Fluor 568, catalog #A21124, Invitrogen; goat anti-rabbit, Alexa Fluor 488, catalog #A11034, Invitrogen; goat anti-chicken, Alexa Fluor 647, catalog #A21449; goat anti-rabbit, Alexa Fluor 568, catalog #A11011, Invitrogen; goat anti-chicken Fluorescein, catalog #F1005, Aves Labs.

Immunostaining

Collected sections were dried at room temperature for 15-30 minutes. PAP pen, catalog #100491-772, was used to delineate create a hydrophobic boundary around sections to contain solutions. Sections were fixed with ice cold 4% paraformaldehyde, EM grade catalog #15710, Electron Microscopy solution, diluted in 1XPBS for 10 minutes and washed twice in PBST (0.05% Triton X-100/1XPBS). Sections were permeabilized in 0.3% Triton X-100/1XPBS for 30 minutes and washed twice in PBST before blocking overnight in 3.2% M.O.M. block/PBST, catalog #BMK-2202, Vector Laboratories at 4°C. After 2 washes in PBST, a second block in normal goat serum (NGS) based blocking buffer (10% normal goat serum, 1%(w/v) blocking powder, catalog #pc2307-1001 FP1020, PerlinElmer Life Sciences, 0.05% Triton X-100, in 1XPBS) was performed for 30 minutes.

Single fibers were fixed in 37°C 2% PFA, EM grade for 10 minutes. PBST washes were performed by removing PFA solution and adding PBST at 1:5 serially three times. Fixed fibers were transferred with horse serum coated fire polished glass pipette

to horse serum glass staining dish and permeabilized using 0.3%Triton X-100/1XPBS for 30 minutes and then washed twice with 1XPBST.

Primary antibody was diluted in NGS-based blocking buffer and applied to sections or fibers overnight at 4°C. After 3 PBST washes, 5 minutes per wash, NGS-based blocking buffer diluted secondary antibody was applied to sections for 30 minutes. DAPI counterstain and 2 additional washes in PBST was performed before mounting in Vectashield mounting medium, catalog #H-1000, Vector Laboratories.

CHAPTER 3: CREB ACTIVITY IS NECESSARY FOR MUSCLE REGENERATION

INTRODUCTION

Choreographed Muscle Regeneration

SCs are the main cellular source for new myofiber formation (Lepper et al., 2011; Murphy et al., 2011; Sambasivan et al., 2011). Muscle repair is a highly regulated process that requires proper activation of SCs for building the cellular source for myofiber formation and SC self-renewal. SCs enter a transit amplification phase in which SCs undergo cell divisions and begin to fuse into new myofibers. Myocytes migrate into an organized linear pattern then fuse to form the multinucleated myofiber (Knudsen et al., 1989; Mintz and Baker, 1967; Yaffe and Feldman, 1965). After fusion, myofibers will begin to grow in size to reestablish the original muscle mass prior to injury (Chargé and Rudnicki, 2004). A portion of proliferating myoblasts will exit the cell cycle, express Pax7, and return to the myofiber niche to serve as a reserve population for future rounds of injury (Fan et al., 2012).

Biological sources for initiation of the muscle regeneration program are disease and injury. Duchenne muscle dystrophy is an X-linked recessive form of muscular dystrophy that is characterized by structurally defective myofibers that undergo cyclic rounds of regeneration and degeneration (Hoffman et al., 1987). Traumatic damage by intense exercise such as weight lifting and eccentric exercise can also induced muscle regeneration (Armstrong et al., 1983; Singh et al., 1999). To generate consistent and robust injuries in controlled experiments, chemical based toxins such as CTX, notexin and barium chloride can be locally injected into skeletal muscle to produce muscle injury. This method is the conventional injury paradigm for studying muscle regeneration.

RESULTS

Genetic strategy to selectively inhibit CREB activity in adult SCs

Forced expression of A-CREB, a potent and selective inhibitor of CREB activity, is routinely used in *in vivo* systems to study CREB function (Ahn et al., 1998b; Herzig et al., 2001; Riccio et al., 1999). Our lab has previously generated a functional mouse allele, *Rosa26^{A-CREB}*, for Cre-dependent A-CREB expression and bicistronic nuclear GFP (nGFP) cell marking (Figure 2A; Lopez and Fan, 2013). After combining this allele with the inducible *Pax7^{CE}* driver (Figure 2A), we could detect nGFP expression in 95% of SCs after tamoxifen administration (Figure 5A,B,C), similar to the cell marking efficiency in *Pax7^{CE};Rosa26^{YFP}* control mice (Figure 5A,B,C). Mice with SC specific A-CREB (*SC_{A-CREB}*) expression did not show altered Pax7⁺ SC number immediately nor over the long-term (Figure 6A,B). To further investigate the maintenance of the SC population, I tested the expression pattern of β 1-integrin and found no disturbance of basal localized expression in *SC_{A-CREB}* (Figure 7A,B). Additionally, break of quiescence was not detected when following EdU incorporation *SC_{A-CREB}* for 3 weeks (Figure 7A,B), which is one week longer than experiments by other groups that found spontaneous proliferation of mutants (Bjornson et al., 2012; Boonsanay et al., 2016; Cheung et al., 2012; Crist et al., 2012; Mourikis et al., 2012; Yamaguchi et al., 2015). The preservation of Pax7⁺ cell number, localization within the niche, and maintenance of quiescent indicates that CREB activity is not required to maintain the SC population during quiescence.

CREB activity is necessary for SC regenerative capacity

Because Pax7⁺ and MyoD⁺ myoblasts showed high pCREB levels, I postulated that CREB might have a role in progenitor expansion after SC activation. I therefore examined muscle regeneration in mice after cardiotoxin (CTX)-induced injury (Figure 8). At 5 and 10 days (d) post-injury, SC_{A-CREB} mice showed significant reductions in regenerated myofiber number and diameter by histology and MHC immunofluorescence (Figure 9A, 10A,B). At 35 d post-injury, the few regenerative fibers at earlier time points were no longer detectable in SC_{A-CREB} mice (Figure 11), consistent with CREB's role in maintaining mature myofiber survival (Berdeaux et al., 2007).

When I assessed the Pax7⁺ population at 5 and 10 d post-injury, SC_{A-CREB} mice showed over 90% fewer Pax7⁺ cells compared to controls (Figure 12). No Pax7⁺ cells were observed in damaged areas 35 d post-injury (Figure 11). Because of the lack of new myofibers, the absence of SCs at 35 d may be due to unavailable myofiber niches. These results indicate that inhibiting CREB in SCs leads to loss of Pax7⁺ SCs after injury, directly or indirectly.

DISCUSSION

The success of regeneration depends on the proper response of SCs to injury stimulus. I found that CREB activity has a distinct role in the regenerative capacity of SCs and muscle regeneration. While CREB inhibition in the SC does not cause stem cell defects in terms of survival, cell fate, nor quiescence, once challenged by injury, SC_{SA-CREB} do not respond correctly to injury stimulus. CREB inhibition leads to drastically reduced myofiber formation (Figure 9A, 10A,B). Newly formed fibers are smaller and fewer are formed, indicating either lack of myocytes fusion or lack of SC proliferation. Because I didn't see an abundance of nGFP positive cells in the interstitial space (Figure 10), I predicted that the inability to form new fibers could be caused by lack of a sufficient progenitor pool rather than a lack of ability to fuse. Because a few fibers do form, a fusion defect likely does not explain the severe inability to regenerate new fibers.

SCs must also self-renew its population to provide a source of stem cells for future rounds of regeneration. The number of Pax7⁺ cells at 5 and 10 days after injury were significantly reduced upon A-CREB expression in the SC lineage. Day 5 is a time point in which a portion of proliferating progenitors have fused to form terminally differentiated myofibers although a portion of myoblasts are proliferating in the interstitial space. At this time point, myoblasts represent both the transit amplifying population as well as the cellular population that will go on to form the reserve SC pool. I found that the number of Pax7⁺ cells was significantly reduced, indicating a lack of expansion of progenitors and/or self-renewing SCs. A further reduction in Pax7⁺ cells at day 10 after injury indicates that the smaller progenitor pool is not due to a delay in

expansion. Further, day 10 after regeneration, SCs will begin to reenter the niche and reestablish quiescence. In A-CREB expressing myoblasts, very few SCs are present compared to control (Figure 12A,B) suggesting A-CREB mice cannot self-renew the SC population after injury.

Figure 5. YFP and nGFP labeling efficiency in the Pax7-lineage (A) Timeline depicting tamoxifen injection regiment and TA muscle harvest 5 days after tamoxifen treatment. METHODS

Mice

Appropriate mating schemes were performed to obtain Pax7^{CE/+}Rosa26^{YFP/YFP} and Pax7^{CE/+}Rosa26^{A-CREB/A-CREB} mice. Animal treatment and care conform to the requirements of institution and NIH guidelines.

Tamoxifen solution

Tamoxifen, catalog #T5648, Sigma, was prepared for intraperitoneal injections by dissolving in corn oil, catalog #C8267, Sigma, at 20 mg/mL. The mixture was incubated in a 37°C shaker at high RPM. Tamoxifen was dissolved within 30-90 minutes and aliquoted into 10mL volumes and flash frozen in dry ice chilled EtOH. Frozen aliquots were stored at -80°C until use. Thawed aliquots were stored at 4°C for up to two weeks.

Tamoxifen injections for inducible Cre activation

250 µL of 20 mg/mL tamoxifen in oil solution was injected daily for 5 consecutive days intraperitoneally into adult mice using a 26 gauge needle.

EdU treatment

200 µL of 0.5 mg/mL EdU solution was injected intraperitoneally into mice daily for 3 weeks.

Cardiotoxin treatment

Cardiotoxin (CTX), catalog #C9759, Sigma, was resuspended in 1XPBS 10 µM and aliquoted into 1.5 mL Eppendorf tubes and flash frozen in dry ice chilled EtOH. Frozen aliquots were stored at -80°C until use. Prior to injection, animals were anesthetized using intraperitoneal injection of Avertin (2,2,2-Tribromoethanol), TCI America at 15

μl/gram body weight of 20 mg/ml solution). TA muscles were injected with 50 μL of CTX using an insulin needle (1/10 mL), catalog #14-829-26, Fisher.

Tibialis anterior (TA) cryosections

See Chapter 2 for methods used for obtaining TA muscle cryosections.

Single fiber isolation

See Chapter 2 for methods used for obtaining single fibers.

Antibodies

Primary antibody used were rabbit anti-GFP monoclonal (1:500), catalog # G10362, Invitrogen; rat anti-Integrinβ1 (1:1000), catalog #MAB1997, Millipore. Secondary antibody used were goat anti-rat AlexaFluor 488 (1:500), catalog #A11077. See Chapter 2 for additional antibodies used.

Immunostaining

See Chapter 2 for methods used for immunostaining muscle tissue sections.

EdU detection

Primary and secondary antibody protocol was performed prior to EdU detection. After secondary antibody application, Click-iT EdU Alexa-Fluor 647 Imaging Kit, catalog #C10085, Invitrogen, was used following manufacture's suggested protocol.

Hematoxylin and Eosin staining

Muscle sections were fixed in ice cold 4% paraformaldehyde for 10 minutes and rinse in distilled water for 1 minute. Sections were incubated in Hematoxylin, catalog #01560, Surgipath, for 3.5 minutes and then rinse in running lukewarm tap water for 5-10 minutes. Sections were then incubated in Scott's tap, catalog #3802901, Leica biosystems, for 10 seconds and then rinsed in running lukewarm tapwater for 2 minutes.

Sections were stained in Eosin, catalog #01600, Surgipath, for 1 minute and dehydrated in EtOH series: dip 5 times in 95% EtOH, dip 5 times in newly made solution of 95% EtOH, dip 30 times in 100% EtOH, dip 30 times in xylene. Sections were mounted under coverslips using PermOUNT, catalog #SP15, Fisher Chemical.

CHAPTER 4: CREB ACTIVITY IS REQUIRED FOR SC PROLIFERATION DURING REGENERATION

INTRODUCTION

Myoblast proliferation during regeneration

Upon injury, SCs undergo proliferation and then differentiation to generate new myofibers (Moss and Leblond, 1970; Snow, 1978). The proper timing of both of these events is crucial for generating sufficient, but not excessive myoblasts. The first SC division after injury can begin as early as 24 hours after injury induction (Zammit et al., 2002). Subsequent cell cycles can be more rapid with a cycling time of about 12 hours being average (Zammit et al., 2002). From day 0 to day 3 of regeneration, SC derived myoblasts are primarily proliferative with only a small portion of cells showing differentiation (Zammit et al., 2004). This allows for expansion of the progenitor pool for supplying the future myonuclei of the regenerated myofibers. After 3 days, the terminal differentiation markers Mgn and MHC begin to appear (Zammit et al., 2004). The beginning of myofiber formation coincides with further myoblast proliferation, however as proliferation ceases, myocyte fusion dominates and myocytes are largely incorporated into myofibers (Robertson et al., 1993).

RESULTS

CREB activity is necessary for SC proliferation

To determine whether the reduction of Pax7⁺ SC_{A-CREB} cells at 5 d post-injury (Figure 12B) is due to defective proliferation, I examined the rate of *in vivo* EdU incorporation during muscle repair from day 0 through 5 after CTX injury (Figure 13A). I observed a marked reduction in SC_{A-CREB} proliferation, compared to robust expansion of control YFP⁺ SCs during the 2-5 d period, when assaying for total lineage marked cells and for percent of cells incorporating EdU at each time point (Figure 13B,C). I next tested whether precocious differentiation might contribute to failed expansion. Indeed, the fraction of lineage marked SCs positive for the myocyte marker Mgn at 2-4 days post-injury were significantly higher in SC_{A-CREB} mice compared to controls (Figure 14). To further test SC_{A-CREB} proliferative performance and differentiation kinetics, I used myofiber culture assays, in which injury is absent. The majority of SC_{S_{A-CREB}} remained as single cells after 3 d in culture, while most control SCs expanded to form multi-cell clusters (Figure 15). At 1 d, when most cells had not undergone cell cycle, single SC_{S_{A-CREB}} expressed Mgn, while control SCs did not (Figure 16), indicating that at least a portion of SC_{S_{A-CREB}} undergo differentiation without cell division. Consistent with our *in vivo* studies, these findings demonstrated that SC_{S_{A-CREB}} proliferate poorly and differentiate early during the expansion phase.

Reduced SC expansion explains fewer newly regenerated myofibers in SC_{A-CREB} mice. However, smaller fiber diameter might also be compounded by reduced fusion

efficiency. To test this possibility, I purified SCs_{A-CREB} and control SCs by fluorescence activated cell sorting (FACS) based on GFP/YFP signal, and plated them at the same density in differentiation media. I found SCs_{A-CREB} showed similar fusion efficiency as controls (Figure 17). Together, the findings provide evidence that SCs_{A-CREB} are defective in proliferation but capable of transitioning through the differentiation program to form new muscle fibers.

DISCUSSION

Expression of A-CREB in the SC causes significantly reduced ability to mount a proliferative program. The lack of proliferation explains the observed regeneration phenotype in which newly regenerated myofibers were reduced as well as their size (Figure 9,10). This indicates that CREB activity promotes a proliferation factor and since few SC_{SA-CREB} expanded or incorporated EdU throughout the expansion period, it is likely that the proliferation defects occurs early. Additionally, myoblast begin to terminally differentiate as early as 1 day after activation (Figure 16), which is usually when the first cell division occurs. These suggest that the first division of SC_{SA-CREB} is defective which leads to loss of an amplifying progenitor pool.

I ruled out the possibility that SC_{SA-CREB} were lost to apoptosis based on their survival after short and long term tamoxifen treatment (Figure 6) as well as their ability to form myofibers in culture without noticeable loss of total cell number (Figure 17). I assayed the differentiation marker Mgn in the A-CREB expressing myoblast population and found a greater percentage of myoblasts had entered terminal differentiation compared to control. This indicated that the loss of proliferation coincides with accelerated differentiation. Loss of RBP-J kappa in SCs also results in accelerated differentiate however these mutant cells also break quiescence and fuse into existing myofibers without injury (Bjornson et al., 2012; Mourikis et al., 2012). This indicates that SC_{SA-CREB} defects likely do not involve Notch signaling completely. The events that regulate the correct balance of proliferation and differentiation are biased towards

differentiation in SC_{SA-CREB}, which leads to severe inability to activate upon injury stimulus.

Figure 13. CREB is required for proper SC proliferation (A) Schematic illustrating tamoxifen treatment and EdU injections used for day 0,2,3,4 and 5 muscle injury regiments. (B) Representative images of EdU incorporation detection in YFP and A-CREB TA muscle at indicated time points after CTX injury. Arrows indicate lineage marked EdU⁻ myoblasts and arrowheads indicated lineage marked EdU⁺ myoblasts. (C) Quantification of YFP and A-CREB lineage-marked myoblast number and EdU⁺ myoblast number on day 0,2,3,4, and 5 after CTX injury. Data represented as mean \pm 1 standard deviation. ** $p < 0.01$, *** $p < 0.001$, Student's t-test. Scale bars 20 μ m.

Figure 14. CREB inhibition leads to premature differentiation (A) Representative images of Mgn expression in YFP and A-CREB myoblasts from TA muscle at 4 days after CTX injury. Data represented as mean \pm 1 standard deviation. * $p < 0.05$, ** $p < 0.01$, Student's t-test. Scale bar 50 μ m.

Figure 15. CREB inhibition in the SC leads to reduced proliferation *in vitro* (A) Representative images of YFP and A-CREB myofiber-associated myoblast clusters after 3 days of culture in plating medium. Arrows indicated lineage marked DAPI-myoblasts from within a cluster. (B) Quantification of cluster size after 3 days of culture in plating medium. Data represented as mean \pm 1 standard deviation. * $p < 0.05$, ** $p < 0.01$, Student's t-test. Scale bar 20 μ m.

Figure 16. CREB inhibition leads to premature differentiation at the expense of Pax7⁺ cell maintenance *in vitro* (A) Immunofluorescence of single myofiber-associated SCs cultured in plating medium for 1 day shows A-CREB SCs undergo premature differentiation. Green arrows mark Mgn⁻ SCs. White arrows mark Mgn⁺ SCs. (B) Quantification of Pax7, MyoD or Mgn expression shows A-CREB SCs have reduced Pax7 and enhanced Mgn. N=3 mice/genotype, n≥100 cells/animal. Data represented as mean +/- 1 standard deviation. **p<<0.01, Student's t-test. Scale bar 10 μ m.

Figure 17. CREB is not necessary for terminal differentiation (A) YFP and A-CREB satellite cells were purified by FACS and plated at equal densities for 5 days in DM. Immunofluorescence analysis of MHC expression shows proper myofiber formation by A-CREB satellite cells. (B) Quantification of fusion index shows A-CREB myoblast differentiation is comparable to control. N=3 technical replicates, $n \geq 200$ cells/replicate. Data is expressed as the mean \pm standard deviation. Scale bar 100 μ m.

METHODS

Mice

See Chapters 2 and 3 for mice used.

Tamoxifen injections for inducible Cre activation

See Chapter 3 for methods used for tamoxifen injections.

Tibialis anterior (TA) cryosections

See Chapter 2 for methods used for obtaining TA muscle sections.

Single fiber isolation

See Chapter 2 for methods used for obtaining single myofibers.

EdU treatment

200 μ L of 0.5 mg/mL EdU solution was injected intraperitoneally into mice 24 hours prior to harvesting muscle tissue for analysis.

Cardiotoxin treatment

See Chapter 3 for methods used for cardiotoxin injury.

EdU detection

See Chapter 3 for methods used for detecting EdU incorporation.

Antibodies

See Chapter 2,3 for methods used for antibodies used.

Fluorescence activated cell sorting (FACS)

SCs of hindlimb muscle from TAM treated YFP and A-CREB mice were isolated in the manner described in “Myoblast isolation” section of methods of Chapter 2. SCs were

resuspended in 1XPBS prior to enrichment by positively selecting for YFP or nGFP signal in lineage marked SCs by FACS.

Tissue culture

FACS sorted myoblasts were cultured on matrigel (1mg/10mL dilution in DMEM), catalog #356234, BD Biosciences, coated Permax tissue culture slides, catalog #62407-335, VWR Scientific, in differentiation media (10% horse serum, PENSTREP, 1% Glutamax, in 1XDMEM).

CHAPTER 5: CREB ACTIVITY PROMOTES SELF-RENEWAL OF THE SC POPULATION

INTRODUCTION

The capacity of SCs to self-renew is evident in their ability to regenerate muscle after multiple rounds of injury. Two studies suggest a role for CREB in cell fate decisions. First, embryonic CREB mutants showed decreased expression of Pax3 (a paralog of Pax7) and MyoD in myogenic progenitors (Chen et al., 2005). Second, germline expression of an activation sensitive form of CREB, CREB-YF, resulted in greater levels of Pax7 protein in myoblasts between 6-12 hours of culturing in differentiation media (Stewart et al., 2011). The inability to regain Pax7⁺ cells during regeneration (Figure 12) and the lack of proliferation of SCs after injury (Figure 13) promoted me to investigate the self-renewal capability of SCs. The role of CREB in cell fate regulation suggests the possible role for CREB in self-renewing the Pax7⁺ population during regeneration.

RESULTS

SCs_{A-CREB} have a defect in self-renewal

Reduced Pax7⁺ cells after injury in SC_{A-CREB} mice suggests a SC self-renewal defect caused either directly by A-CREB expression in the SCs and/or secondarily by deficient newly formed myofiber niches and inadequate environmental conditions of poorly regenerated areas. The myofiber culture assay permits SC self-renewal examination within wild-type niches and adequate milieu (Day et al., 2007; Zammit et al., 2004). By assessing the fractions of lineage marked Pax7⁺MyoD⁻ (self-renewed), Pax7⁺MyoD⁺ (expanding progenitors), and Pax7⁻MyoD⁺ (committed progenitors) cells 4 d after activation, I found that the SC_{A-CREB} lineage had reduced fractions of expanding progenitors and renewed SCs (Figure 18A,B). Furthermore, I found that FACS purified SCs_{A-CREB} generated fewer Pax7⁺ reserve cells compared to controls in 5 d differentiated cultures (Figure 19A,B). As reserve cells are suggested to be similar to quiescent SCs, SCs_{A-CREB} may be defective in re-acquiring quiescence.

I next examined SC symmetric versus asymmetric divisions by probing for Pax7, MyoD or Mgn expression after the first cell cycle in myofiber cultures. In 2 d cultures, 80% of control SCs divided once to form doublets, whereas only 23% of A-CREB clusters were doublets (Figure 20). Over 80% of control doublets contained at least one Pax7⁺ daughter, conversely over 80% of A-CREB daughters were both Pax7⁻ (Figure 21B). Both YFP and A-CREB doublets were mostly MyoD⁺ (Figure 21B). Notably, many A-CREB doublets contained daughters that were both Mgn⁺, whereas this combination was rarely seen in controls (Figure 21A,B). Based on the observation that SC self-

renewal occurs in the first cell division (Troy et al., 2012), these data show that the small fraction of $SC_{SA-CREB}$ that divide have a high propensity towards differentiation and limited self-renewal. All together, I conclude that CREB activity maintains the $Pax7^+$ SC population after they are activated.

DISCUSSION

Self-renewal is a hallmark characteristic of SCs, which enables multiple rounds of muscle repair throughout the lifetime of the organism. CREB inhibition in the SC abolishes the capacity to maintain the Pax7⁺/MyoD⁻ self-renewing population as well as the Pax7⁺/MyoD⁺ progenitor population after activation (Figure 18). This occurs on single fiber cultures in which the myofiber niche is not disrupted by damage and has not incorporated defective myoblasts. This shows that the SC_{A-CREB} defect *in vivo* (Figure 9, 10,11,12,13,14) is not merely a secondary effect of disrupted myofibers and altered niche. Consistently, FACS purified A-CREB expressing cultured myoblasts could not reform the reserve cell phenotype (Figure 19). Therefore, the requirement for CREB in the ability to re-establish the Pax7⁺ lineage is likely cell autonomous.

Upon activation, SCs are thought to be a heterogeneous mixture of myoblasts that have differential propensities towards self-renewal or differentiation (Kuang et al., 2008). In a recent study to determine when the SC might be committed for self-renewal, the authors found that SCs that regained quiescence at 4 days after activation (the reserve cell phenotype) were set aside during the first cell division (Troy et al., 2012). The inhibition of CREB in the SC prior to activation led to mostly an inability to expand (Figure 20), and those SCs that did undergo one cell division had high propensity to differentiation rather than self-renew (Figure 21). The direct terminal differentiation without proliferation explains some of the reason why few cells divide (Figure 16). Both the inability to proliferate as well as the accelerated differentiation rate of SC_{SA-CREB} contribute to their lack of self-renewal.

Figure 18. CREB inhibition leads to loss of Pax7 self-renewal after activation (A) Single myofiber-associated SCs were cultured for 4 days. Immunofluorescence analysis of myoblasts within clonal clusters. Red and green arrows mark Pax7⁺MyoD⁻ and Pax7⁻/MyoD⁺ myoblasts, respectively. Asterisks mark Pax7⁺MyoD⁺ myoblasts. (B) Quantification of Pax7 and MyoD expression pattern shows few SCs_{A-CREB} renew the Pax7⁺/MyoD⁻ population after activation. N=3 mice/genotype, n≥150 cells/animal. ##p<0.01 Chi-squared test. Scale bar 20 μm.

Figure 19. CREB inhibition leads to loss of Pax7⁺ reserve cell population (A) YFP and A-CREB expressing SCs were purified by FACS and plated at identical densities for 5 days in DM. Immunofluorescence analysis of Pax7 shows reduced Pax7⁺ population in SCs_{A-CREB}. Arrows mark Pax7⁺ myoblasts. (B) Quantification of Pax7⁺ cell number after differentiation shows SCs_{A-CREB} reestablish fewer Pax7⁺ reserve cells. N=3 technical replicates, n≥200 cells/replicate. Data represented as mean +/- 1 standard deviation. **p<0.01 Student's t-test. Scale bar = 50 μm.

Figure 20. Proliferative cluster profile of SCs after 2 days in culture Quantification of cell number within myofiber-associated YFP and A-CREB myoblast clusters 2 days after activation. $n \geq 100$ cells/genotype.

Figure 21. CREB inhibition leads to loss of Pax7⁺ expression after the first cell division (A) EDL myofibers and associated SCs were cultured for 2 days in plating media. Immunofluorescence analysis of myoblast doublets. Mgn expression within myoblast doublets shows increased frequency of Mgn expression by SCs_{A-CREB}. White and red arrows mark Mgn⁻ myoblasts and Mgn⁺ myoblasts, respectively. (B) Quantification Pax7, MyoD, or Mgn expression within doublets. N=3 mice/genotype/marker, n≥50 doublets/marker/animal. ##p<0.01 Chi-squared test. Scale bar 20μm.

**CHAPTER 6: IDENTIFICATION OF CREB-DEPENDENT POLARITY
PROTEIN MPP7 BY RNA-SEQ**

INTRODUCTION

CREB regulation of transcription has been a long-term focus of studies. Since its original discovery as a transcriptional regulator of *somatostatin* in the nervous system (Montminy et al., 1986), hundreds of direct targets have been predicted for CREB and a subset have been validated based on gene expression levels, binding assays and sequencing analysis. The advent of high throughput sequencing has allowed for the discovery of non-canonical CREB family binding sites, in additional CREB responsive elements (CREs). ChIP-seq assays have determined these are actively transcribed CREB binding sites and are able to activate downstream targets (Martianov et al., 2010; Mayr and Montminy, 2001). Using a comparative RNA-seq approach to determine genes that are directly or indirectly regulated by CREB along with ChIP-PCR to determine direct binding of CREB to conventional and novel CRE sites, I have discovered the transcriptional changes that are important for CREB-mediate SC function, as described below.

RESULTS

Identification of CREB downstream genes in quiescent SCs

To ascertain the mechanism by which CREB controls SC proliferation and self-renewal, I identified CREB transcriptional targets in SCs. SCs_{SA-CREB} display precocious Mgn expression after injury/isolation, signifying early onset of defects. Therefore, to improve our prospects of finding primary CREB targets responsible for this effect, I harvested freshly isolated control and SCs_{SA-CREB} from hind limb muscles by FACS for immediately RNA preparation and RNA-seq. Although CREB family members are transcriptional activators, there was a much larger set of up-regulated (1517) than down-regulated (17) genes in SCs_{SA-CREB} compared to controls (Figure 22, Table 1, Table 2). A KEGG pathway database search (Huang et al., 2009a, 2009b) using the up-regulated gene set as input did not reveal pathway changes that could suggest abnormal signal transduction of SCs_{SA-CREB} (Table 3). Rather, 81 up-regulated genes could be categorized into 38 KEGG pathways, with many of them being metabolic pathways (Table 4), which has already been linked to CREB function (Altarejos and Montminy, 2011).

For identifying primary CREB targets, I focused on the 17 downregulated genes (Table 2). Using bioinformatics to query their promoter regions (-5kb - +1kb of the transcription start site), I found 16 of these genes contained at least one half-CRE and/or novel half-CRE site (Martianov et al., 2010); half-CRE sites have been shown to be highly functional in enhancing transcription of gene targets (Lesiak et al., 2013; Mayr and Montminy, 2001). Using the CREB database search tool (Zhang et al., 2005), 3 genes were found to contain CRE sites near a TATA box and 1 gene contained a CRE site

without a proximal TATA box (Table 2). *Nr4a2* and *Nr4a3* are canonical CREB target genes that are essential for dopaminergic differentiation and oncogenic functions, respectively (Ke et al., 2004; Le et al., 2003). The remaining genes have no documented function in SC proliferation or self-renewal. I chose to focus on *Mpp7*, because it is a polarity protein with tangential links to both aspects of SC function in the literature.

SC_{SA-CREB} display altered apical protein distribution

Mpp7, the membrane-associated guanylate kinase (MAGUK) p55 subfamily member 7, is a homolog to *Drosophila* polarity protein Stardust. It shows the highest transcriptional change (≥ 10 fold) of the down-regulated genes within SC_{SA-CREB} (Table 2) and greatest transcriptional abundance among the 7 *Mpp* family members (Figure 23). Chromatin immunoprecipitation (ChIP) analysis of SC-derived myoblasts confirmed pCREB binding to two predicted half-CRE sites in the *Mpp7* promoter (Figure 24) suggesting its regulation by CREB. *Mpp7* has been studied in epithelial cell lines and shown to localize to adherens junctions and tight junctions for their maintenance (Bohl et al., 2007; Stucke et al., 2007). To determine *Mpp7* distribution in SCs, I analyzed 3-D reconstructed immunofluorescence images of freshly isolated SCs on myofibers and found *Mpp7* was preferentially localized to the apical side, opposite to $\alpha 1$ -integrin basal localization, in the majority of SCs (Figure 25A-E). Consistent with *Mpp7* being a target of CREB, the majority of SC_{SA-CREB} displayed low to undetectable *Mpp7* (Figure 25D,E).

This prompted me to ask whether additional SC polarity proteins were affected in SC_{SA-CREB}, irrespective of direct CREB regulation. M-cadherin and its intracellular effector β -catenin are both localized to the apical surface of SCs (Figure 26A,C,G,I). M-cadherin is restricted apically in quiescent SCs, but invaded the basal domain of SC_{SA-}

β -catenin (Figure 26B,C). Similarly, the altered pattern of β -catenin localization followed that of M-cadherin (Figure 26H,I). Because SCs_{A-CREB} are defective in proliferation, I examined the localization of a SC activation determinant, polarity protein Par-3. Unexpectedly, it was drastically reduced in SCs_{A-CREB}, compared to its apically concentrated pattern in control SCs (Figure 26D-F). Conversely, distribution of the basally enriched α 1-integrin was unperturbed in SCs_{A-CREB} (Figure 26J-L), consistent with *in vivo* localization pattern during quiescence (Figure 7A). All together, these data suggest that SCs_{A-CREB} have a partial defect in maintaining apical polarity, while retaining the basal domain.

DISCUSSION

CREB activity has been implicated in myoblast proliferation (Stewart et al., 2011) however its role in the SC has not been determined. Here, I found that it has a direct role in promoting the expression of transcript and protein of Mpp family member Mpp7, the membrane-associated guanylate kinase (MAGUK) p55 subfamily member 7 (Figure 23, 24, 25). Mpp family has PDZ domains that allows for protein-protein interactions and categorized as a scaffolding protein (Bohl et al., 2007; Stucke et al., 2007). Mpp7 has been found to be required for proper tight junction function and localized to tight and adherens junction (Bohl et al., 2007; Stucke et al., 2007). Here, I found that Mpp7 colocalizes to the apical domain as does β -catenin, an adherens junction associated protein (Figure 25A-E, 26G-I). Mpp7, is a homolog to *Drosophila* polarity protein Stardust of *Drosophila*. Stardust is apically localized in *Drosophila* epithelial cells usually through interactions with its binding partner Crumbs (Bachmann et al., 2001). Interestingly, mammalian Crumbs paralogs are not expressed in SCs as assessed by RNA-seq of a very low FPKM (data not shown). This provides evidence that Mpp7 does not coordinate with the conventional Crumbs containing Stardust complex in SCs.

CREB inhibition in SCs did not cause a loss in SCs (Figure 5A-C, 7) however I found a redistribution of polarized localization of proteins (Figure 25, 26). By immunofluorescence, Mpp7 was enriched on the apical side of quiescent SCs. Consistent with the role of CREB in regulating Mpp7 expression, SCs_{A-CREB} had reduced Mpp7 expression. Furthermore, M-cadherin, Par-3 and β -catenin were mislocalized or reduced (Figure 26). This shows that there is a distinct defect in the apical domain during quiescence.

Interestingly, Par-3 has a role in SC progenitor expansion (Troy et al., 2012) which is consistent with the lack of proliferation of SCs_{A-CREB}.

Figure 22. Flowchart followed to identify candidate CREB targets in quiescent satellite cells by RNA-seq (A) YFP and A-CREB satellite cells were purified by FACS and subjected to RNA-seq analysis. Transcriptome comparison performed using Cufflinks.

Scale bars 10 μ m.

METHODS

Mice

See Chapters 2 and 3 for mice used.

Illumina cDNA sequencing (RNA-seq)

High quality (RIN>9) total RNA was isolated from FACS sorted cells using Arcturus Pico kit, catalog #KIT0204, Applied Biosystems. 70 ng of total RNA was then used as starting material for Ribozero rRNA depletion, catalog #RZH1086, Epicentre (Illumina). cDNA was generated from this rRNA depleted sample following Illumina TruSeq DNA sample prep (low input), Illumina.

Library read mapping

For RNA-seq, reads were aligned to mm9 UCSC version 7 mouse genome. Tuxedo protocol (Trapnell et al., 2012), Tophat and cufflinks, was followed to determine relative expression levels of genes. 2 biological replicates were used per experimental sample and control.

ChIP-PCR

Fragmented chromatin was obtained from 4×10^6 myoblasts grown in growth media (20% fetal bovine serum, 5% horse serum, 1% chicken embryo extract, PENSTREP, 1% Glutamax, bFGF) using Covaris truChIP low cell chromatin shearing kit, catalog #010145, Covaris. Cells were fixed in 1% formaldehyde for 10 minutes and chromatin was sonicated using Covaris M22 Focused ultrasonicator, peak power 75, duty factor 5, cycles/burst 200, 6°C using 30 second pulses at 2 minute intervals at 6W for 8 minutes of total sonication time to generate chromatin 200-1000bp in size. Antibodies used for IP:

anti-phospho-Ser133-CREB, catalog #9198 (87G3), Cell Signaling; anti-normal rabbit IgG, catalog #2729, Cell Signaling. Immunoprecipitated DNA was purified by QIAquick PCR Purification kit. Primers used to detect Mpp7 promoter motif 1: 5'- CAG CGT CTG GCT ATG TGC C-3', 5'- CCA GGC ATG ATA GCA CAT GG-3'; motif 2: 5'- TGC ACC TCC CAG CGA GAC-3', 5'- GCT CAG CAG GAT GAA CTA GC-3'; motif 3: 5'- GCT AGT TCA TCC TGC TGA GC-3', 5'- CAG TCC AAG CGC CAC TTA G-3', motif 4: 5'- GTG TAA CAA GGA AGT GTG TGA TG-3', 5'- CTT GCC TAA TAG GCA CAT GAC T-3'

Single fiber isolation

See Chapter 2 for methods used for obtaining single fibers.

Antibodies

Primary antibodies used were rabbit anti-Mpp7 (1:10), catalog #12983-1-AP, Proteintech; goat anti-Mpp7 (1:25), catalog #sc-163089, Santa Cruz; mouse anti-M-cadherin (1:250), catalog #81471, Santa Cruz; rabbit anti-Par-3 (1:250), catalog #07-330, Millipore; mouse anti- β -catenin IgG1 (1:100), catalog #RDI-BCATENIN, RDI. See Chapter 2,3 for additional antibodies used.

CHAPTER 7: MPP7 MEDIATES MYOBLAST PROLIFERATION AND SELF-RENEWAL

INTRODUCTION

Cellular quiescence and proliferation are regulated by polarity proteins in multiple stem cell systems (Florian and Geiger, 2010). The functional relevance of polarity during quiescence is unclear, however the importance of polarity during activation has been studied. The polarity protein Mark2 (Par1b) is basally localized in activated SCs and regulates asymmetric division (Dumont et al., 2015). The Scrib polarity protein, localized basolaterally in epithelia (Su et al., 2012), is critical for promoting myoblast proliferation and differentiation (Ono et al., 2015). Polarity proteins mediate SC divisions and cell fate through activation of signaling pathways. p38 α / β MAPK pathway is activated by the core apical polarity complex components Par-3 and PKC λ during SC expansion to promote transit amplification *in vitro* (Troy et al., 2012). Given the requirement for polarity proteins during SC expansion, the significance of polarity during quiescence warrants further attention.

I found that Mpp7 polarity protein was the most highly down-regulated transcripts in SC_{SA-CREB} (Table 2). This defect in polarity could be a secondary effect of another misregulated gene. In order to rule out this possibility, I tested the contribution of Mpp7 to the proliferation and self-renewal capacities of SCs.

RESULTS

Mpp7 expression rescues the proliferation and self-renewal defect of SCs_{SA-CREB}

To test whether Mpp7 is a downstream mediator of CREB function in the SC, I introduced constructs for expressing Mpp7 together with bicistronic membrane-GFP (mGFP) or mGFP alone into SCs_{SA-CREB} on their myofibers; mGFP was used to follow transfected cells in conjunction with SCs_{SA-CREB} nGFP. Expression of Mpp7 increased SCs_{SA-CREB} proliferative cluster sizes and expanded both the Pax7⁺MyoD⁺ progenitor and Pax7⁺MyoD⁻ self-renewed fractions (Figure 27A-C). In parallel, I transfected the same constructs into unmarked wild-type SCs. Mpp7 expression did not alter proliferative cluster sizes, but rather increased the fractions of Pax7⁺MyoD⁺ progenitors and Pax7⁺MyoD⁻ self-renewed SCs (Figure 27A-C). Importantly, Mpp7 rescued the proliferative cluster size profiles, Pax7⁺MyoD⁺ fractions and Pax7⁺MyoD⁻ fractions of SCs_{SA-CREB} to levels equivalent to those in control SCs expressing mGFP alone (Figure 27). These data support Mpp7 is not only a target but also a functional mediator of CREB activity.

I next tested whether Mpp7 knockdown by siRNA is sufficient to cause an expansion defect in control YFP⁺ cells. I was not able to achieve successful siMpp7 knockdown in myofiber cultures, therefore I turned to SC-derived myoblasts, which also display high CREB activity (Figure 4A,B) and express *Mpp7* (Figure 25). As expected, A-CREB expression in SC-derived myoblasts showed compromised proliferation and increased differentiation (Figure 28). I tested 3 siRNAs against *Mpp7* transcripts and the 2 that were effective in reducing *Mpp7* expression (Figure 29) exhibited decreased EdU

incorporation and increased Mgn expression relative to scrambled control siRNA (Figure 30). All together, these data indicate that Mpp7 is a major downstream mediator of CREB function in SCs and myoblasts.

DISCUSSION

Polarity protein Mpp7 is highly downregulated (Figure 23) and apically localized proteins are also distributed aberrantly (Figure 26A-I) in SCs_{A-CREB}. Interestingly, Par-3, an activation promoting polarity protein, is absent or reduced in SCs_{A-CREB} (Figure 26D-F) suggesting that an overall defect in polarity may contribute to the lack of proliferation and self-renewal of SCs_{A-CREB}. I found that re-expressing Mpp7 alone is sufficient to restore the ability of SCs_{A-CREB} to proliferate and self-renew (Figure 27). Interestingly, overexpression of Mpp7 in wild-type SCs also increased the proportion of self-renewing and progenitors populations (Figure 27) although proliferation did not change. The ability for Mpp7 to positively direct proliferation and self-renewal is a novel function for Mpp family of proteins and a novel role for a polarity protein in quiescent SCs. Given the high level of Mpp7 during quiescence and polarity defect of SCs_{A-CREB}, these data provide evidence that setting up a polarity during quiescence affects future potential for activation and self-renewal.

Figure 27. Overexpression of Mpp7 in SCs_{A-CREB} cells rescues proliferation defect and Pax7⁺ cell population loss (A) EDL single fibers and associated SCs of A-CREB and CD1 mice were transfected with Mpp7::mGFP or mGFP and cultured in plating medium for a total of 4 days. Representative images of clonal clusters showing cluster size and Pax7⁻/MyoD⁺, Pax7⁺/MyoD⁻, or Pax7⁺/MyoD⁺ expression patterns. (B) Quantification of clonal cluster size after transfection with Mpp7::mGFP or mGFP. (C) Quantification of Pax7⁻/MyoD⁺, Pax7⁺/MyoD⁻, or Pax7⁺/MyoD⁺ expression patterns after transfection with Mpp7::mGFP or mGFP. ##p<0.01, Chi-squared test. Scale bars 25 μ m.

Figure 28. CREB inactivation in cultured myoblasts causes reduced proliferation and premature differentiation Primary myoblasts harvested from Pax7^{CE/+};Rosa26^{YFPYFP} and Pax7^{CE/+};Rosa26^{A-CREB/A-CREB} (TAM-) mice were cultured in growth medium for 1 passage and treated with 1μM 4-Hydroxytamoxifen for 24 hours. (A) Quantification of Pax7⁺, EdU⁺ or Mgn⁺ lineage marked myoblasts 24 hours after 4-Hydroxytamoxifen treatment. **p<0.01, Student's t-test.

Figure 29. siRNA targeting *Mpp7* transcripts reduces *Mpp7* levels (A) 3 siRNAs targeting different regions of the *Mpp7* transcript were tested for ability to reduce *Mpp7* levels as detected by qRT-PCR. Data represented as mean \pm 1 standard deviation. ** $p < 0.01$, Student's t-test.

Figure 30. Knockdown of *Mpp7* transcripts leads to reduced proliferation and enhanced differentiation of cultured myoblasts TAM-treated YFP SCs were harvested and cultured in growth medium. Cell were transfected twice in 24 hour increments with indicated siMpp7 combinations. Analysis was performed 24 hours after last transfection. (A) Representative images of immunofluorescence detection of EdU and Mgn in siMpp7 and siScr (control) experiments. (B) Quantification of EdU incorporation and Mgn expression. Data represented as mean \pm 1 standard deviation. ** $p < 0.01$, Student's t-test.

METHODS

Mice

See Chapters 2 and 3 for mice used.

Single fiber isolation

See Chapter 2 for methods used for obtaining single fibers.

Plasmids

The backbone vector pMIGR1 (Pear et al., 1998) was modified to replace the GFP gene with EGFP-CAAX (membrane GFP, mGFP) to serve as a control. Human Mpp7 cDNA with a V5 C-terminal tag was cloned into the pMIGR1-mGFP to produce pMIGR1-V5Mpp7-IRES-mGFP. Each plasmid expresses membrane GFP as a reporter for transfection efficiency.

siRNAs

siRNAs targeting mouse *Mpp7* were purchased from Life Technologies, catalog #s: s93843 (#1), s93844 (#2), s93845 (#3), and resuspended to 20 μ M working concentration. Silencer Select Negative Control siRNA, catalog #4390843, Life Technologies, was used as a control.

qPCR and primers

Total RNA was isolated from cells using Arcturus Pico kit, catalog #KIT0204, Applied Biosystems. cDNA was generated following standard methods using NEB M-MuLV Reverse Transcriptase, catalog #M0253S, New England BioLabs. Quantitect SYBR Green PCR Kit reagent, catalog #204141, Qiagen, was used in quantitative PCR reactions in a BioRad Thermocycler, catalog #CFX96 PCR, BioRad, for PCR product detection. *Mpp7* transcript was detected using primers forward: 5'-AGG ATC GGC TTG CGA

CAT G-3' and reverse: 5'-ACA CGT CCC AGA GGA AGG TC-3'. *18S RNA* levels were determined using primers forward: 5'-GTA ACC CGT TGA ACC CCA TT-3' and reverse 5'-CCA TCC AAT CGG TAG TAG CG, as an internal control.

Single fiber transfection of plasmids

Single fibers were isolated as described in Chapter 2 and cultured in, growth media (20% fetal bovine serum, 5% horse serum, 1% chicken embryo extract, PENSTREP, 1% Glutamax, bFGF), for 8 hours on horse serum coated tissue culture dishes. Transfection solution was prepared using TransfeX reagent, catalog#ACS-4005, ATCC, at DNA(ug):TransfeX TransfeX reagent, at 1:2 ratio for 12 hours. Media was changed to plating media for the remainder of the culture for a total of 4 days after initial harvest.

Myoblast transfection of siRNAs

Plated myoblasts were cultured on matrigel coated tissue culture dishes and grown to 50% confluency prior to transfection. siRNAs were diluted in OPTIMEM and combined with Lipo 3000 reagent at 1:1 ratio following manufacture's protocol, catalog #L3000008, Life Technologies. Transfections were performed for 6 hours after which fresh plating media (10% horse serum, 0.5% chicken embryo extract, 1XPENSTREP, 1% Glutamax) was added to cells. 24 hours after the first transfection, a second transfection under the same conditions was performed. 24 hours after second transfection, myoblast were analyzed.

Antibodies

See Chapter 2 for antibodies used.

EdU treatment

EdU was added to tissue culture media at 10 μ M final concentration for 2 hours prior to analysis.

EdU detection

See Chapter 3 for EdU detection methods.

**CHAPTER 8: MPP7 PROMOTES PROLIFERATION AND SELF-RENEWAL
VIA AMOT-YAP**

INTRODUCTION

The Hippo pathway effector YAP promotes myoblast proliferation and inhibits differentiation (Judson et al., 2012; Tremblay et al., 2014). Interestingly, polarized subcellular Angiomotin (AMOT) distribution differentially regulates Hippo signaling to direct YAP-dependent cell fate in pre-implantation embryos (Hirate et al., 2013; Leung and Zernicka-Goetz, 2013). YAP is repressed by core Hippo pathway kinases Mst1/2 and Lats1/2 YAP (Pan 2010), whereas it is either activated or repressed by AMOT family of proteins (consisting of AMOT, AMOTL1, and AMOTL2), depending on the cellular context (Chan et al., 2011; Yi et al., 2013; Zhao et al., 2011). Discriminating factors modulate AMOT activity and a seminal study identified Par-3, AMOTL1, AMOTL2, and tight junction associated *Drosophila* Stardust homologs, Mpp5 and Mpp7 to be AMOT binding partners (Wells et al., 2006). Whether Mpp7, and AMOT affect YAP activity in SCs is unknown. Moreover, the transcriptional regulation of polarity genes has not been investigated in SCs.

RESULTS

Mpp7 and AMOT regulate myoblast proliferation and YAP nuclear accumulation

I next sought to determine the mechanism by which how Mpp7 regulates proliferation. Among the Mpp7 protein interactions (Bohl et al., 2007; Stucke et al., 2007; Wells et al., 2006), an AMOT-containing complex (Wells et al., 2006) is of particular interest due to the critical role for AMOT in regulating Par-3 and YAP, both known proliferation regulators of SCs (Judson et al., 2012; Troy et al., 2012). Like Mpp7, AMOT is localized to the apical side of quiescent SCs (Figure 31A-E). By double labeling, I found overlapping signals between Mpp7 and AMOT (Figure 31D,E). Proximity ligation assay (PLA) confirmed this apical interaction between Mpp7 and AMOT (Figure 32). Furthermore, a portion of Mpp-AMOT and Mpp7-YAP PLA signals were localized to the SC nucleus of a portion of SCs (Figure 32,33,34), suggesting a possible role of AMOT and Mpp7 for YAP nuclear shuffling, previously observed in hepatocytes (Yi et al., 2013). Most SCs_{SA-CREB} displayed reduced AMOT (Figure 35) even though AMOT transcripts were not reduced (Figure 36), suggesting a translational or post-translational change. For the subset that exhibited a detectable level of AMOT, the expression pattern was almost exclusively non-polarize (Figure 35B). I next examined whether YAP also displayed aberrant expression. I found YAP accumulated in the nucleus in control quiescent SCs, but it was severely reduced in SCs_{SA-CREB} (Figure 37A,B). The lack of YAP target genes (Piccolo et al., 2014) in the SCs_{SA-CREB} down-regulated group (Table 2) suggests that YAP's transcriptional action is minimal in quiescent SCs, but becomes permitted after SC activation, i.e. after SC quiescence is lifted.

A constitutively active form of YAP, that can accumulate in the nucleus, enhanced proliferation and reduced differentiation of C2C12 and SC-derived myoblasts (Judson et al., 2012; Watt et al., 2010). To test whether Mpp7 and AMOT, as well as other potential regulators, play a role in YAP nuclear accumulation of myoblasts, I used an RNAi approach. After testing 3 different siRNAs per gene (Figure 38), I selected the siRNA with the most effective knockdown for the remainder of experiments. RNAi of *Mpp7*, *AMOT*, or AMOT family members *AMOT-L1* and *AMOT-L2*, each caused reduction of EdU⁺ proliferating and Pax7 expressing cells, while increased Mgn⁺ cells (Figure 39). Additionally, nuclear YAP was reduced (Figure 40). Confirming previous work, RNAi of YAP strongly reduced myoblast proliferation and Pax7⁺ cells, while increased Mgn⁺ cells (Figure 39). Furthermore, RNAi of Mpp7 caused down-regulation of canonical YAP downstream genes (Figure 41). To test the contribution of the Hippo pathway, I targeted Lats1 and Lats2, the immediate upstream kinase negative regulators of YAP. RNAi of *Lats1* and/or *Lats2* enhanced proliferation, nuclear YAP, and Pax7 expression without affecting Mgn expression (Figure 39,40). The similarities among *Mpp7*, *AMOT* family and *YAP* RNAi, and the biochemical data of Mpp7-AMOT family (Wells et al., 2006) and AMOT-YAP (Chan et al., 2011; Yi et al., 2013; Zhao et al., 2011) protein complexes led me to propose that they form a regulatory axis that promotes proliferation and dictates myogenic fates of myoblasts.

DISCUSSION

Here, I have shown that Mpp7 directs an AMOT-YAP axis to regulate SC proliferation and Pax7 expression. Previous studies showed that Mpp7 and AMOT family members interact in HEK293T cells (Wells et al., 2006) and consistently I found that Mpp7 interacts with AMOT in SCs (Figure 32,33,34). Based on previous studies of AMOT and YAP interactions, the effect of AMOT on YAP activity could be either positive or negative depending on cellular context (Chan et al., 2011; Yi et al., 2013; Zhao et al., 2011). My data provides evidence for the former, in which AMOT is a positive regulator of YAP (Figure 40). This is consistent with the idea that overexpression of AMOT family members in cell lines might have a negative effect on YAP whereas biologically relevant levels of AMOT positively regulate YAP (Yi et al., 2013). In summary these data show that Mpp7 is a positive regulator of AMOT in the SC to promote YAP signaling.

The mechanism by which AMOT regulates YAP has been controversial. The sequestering of YAP by AMOT in the cytoplasm has been suggested (Chan et al., 2011, 2013; Wang et al., 2011; Zhao et al., 2011) as well as enhancing YAP nuclear entry by AMOT to promote YAP downstream target gene activation (Yi et al., 2013). SCs show nuclear localization of Mpp7-YAP interactions, indicating that Mpp7 may also be involved in the nuclear transport of YAP. Based on my localization studies, Mpp7 is found both on the apical membrane as well as the nucleus, and one scenario for YAP regulation may be that Mpp7 can promote transport of YAP into the nucleus, or at least protect it from degradation, through cooperation with AMOT.

Figure 31. AMOT is localized to the apical domain of SCs (A) 3-dimensional (3-D) reconstruction of confocal images obtained from single myofiber-associated SCs. Letters mark b-basal, m-medial, a-apical planes parallel to the myofiber long axis and T-transverse plane orthogonal to the myofiber long axis. (B) Representative image of digital transverse slice of SCs obtained from 3-D reconstruction. (C) Images rendered from basal (b), medial (m), and apical (a) planes delineated in (A). AMOT immunofluorescence I.D. shows AMOT is enriched in the medial and apical domains. METHODS

Mice

See Chapters 2 and 3 for mice used.

Single fiber isolation

See Chapter 2 for methods used for obtaining single fibers.

Antibodies

Primary antibodies use were rabbit anti-AMOT, catalog #sc-98803, Santa-Cruz; rabbit anti-YAP/TAZ, catalog #8418S, Cell Signaling. See Chapter 2,3, and 6 for additional antibodies used.

Proximity Ligation Assay (PLA)

Single fibers were obtained using the methods described in Chapter 2. Primary antibody application was performed as described in Chapter 2. PLA was performed per manufacture's protocol, Duolink In Situ Red Started Kit Goat/Rabbit, catalog #DUO92105, Sigma. In short, after primary antibody application, PLUS and MINUS PLA probes were added to samples and then a ligation reaction performed to join probe ends. Amplification of the probe linkers were performed in the presence of fluorescently labeled nucleotides for detection of protein-protein proximity. Secondary antibody application was performed as described in Chapter 2. Samples were mounted under coverslips using Duolink in situ fluorescence medium, provided in the kit. For the negative control reaction, only one primary antibody was used and the same protocol was performed as described above.

qPCR and primers

See Chapter 7 for methods for cDNA generation, qPCR, and primers for detecting *Mpp7* transcripts. *AMOT* transcript was detecting using primers forward: 5'- CCG CCA GAA TAC CCT TTC AAG -3' and reverse: 5'- CTC ATC AGT TGC CCC TCT GT -3'; *AMOTL1* transcript was detecting using primers forward: 5'- ATG TAG CCT CTG GAA GAG TGT -3' and reverse: 5'- TGA GTG AGG GTT TCC GTG GA -3'; *AMOTL2* transcript was detecting using primers forward: 5'- GGA GAA GAG TTG CCC ACC TAT -3' and reverse: 5'- TCG AAG AGC TTC ATC CTG TCG -3'; *YAP1* transcript was detecting using primers forward: 5'- ACC CTC GTT TTG CCA TGA AC -3' and reverse: 5'- TGT GCT GGG ATT GAT ATT CCG TA -3'; *Lats1* transcript was detecting using primers forward: 5'- AAA GCC AGA AGG GTA CAG ACA -3' and reverse: 5'- CCT CAG GGA TTC TCG GAT CTC -3'; *Lats2* transcript was detecting using primers forward: 5'- GGA CCC CAG GAA TGA GCA G -3' and reverse: 5'- CCC TCG TAG TTT GCA CCA CC -3'; *ANKRD1* transcript was detecting using primers forward: 5'- TAA TCG CTC ACA ATC TGT TGA CA -3' and reverse: 5'- GCC TCT CAC CTT CCG ACC T -3'; *Areg* transcript was detecting using primers forward: 5'- GCA GAT ACA TCG AGA ACC TGG -3' and reverse: 5'- CTG CAA TCT TGG ATA GGT CCT TG -3'; *Birc5* transcript was detecting using primers forward: 5'- CTG GGA ACC CGA TGA CAA C -3' and reverse: 5'- TGG CTC TCT GTC TGT CCA G -3'; *CTGF* transcript was detecting using primers forward: 5'- GGG CCT CTT CTG CGA TTT C -3' and reverse: 5'- ATC CAG GCA AGT GCA TTG GTA -3'. *18S RNA* transcript levels were used as internal controls. See Chapter 7 for *18S RNA* primers.

siRNAs

See Chapter 7 for siRNA targeting mouse *Mpp7*. The following siRNAs were purchased from Life Technologies targeting mouse *AMOT*, catalog #s: s77828 (#1), s77829 (#2), s77830 (#3); mouse *AMOTL1*, catalog #s: s93825(#1), s93826(#2), s93827(#3); mouse *Lats1*, catalog #s: s201588 (#1), s201589 (#2), s201590 (#3); mouse *Lats2*, catalog #s: s78350 (#1), s78351 (#2), s78352 (#3), mouse *YAP1*, catalog #s: s76159 (#1), s76160 (#2), s202423 (#3). siRNAs targeting mouse *AMOTL2* were purchased from Sigma, catalog #s: SASI_Mm02_00324945 (#1), SASI_Mm02_00324945 (#2), SASI_Mm02_00324945 (#3). All siRNAs were resuspended at a 20 μ M working concentration.

EdU treatment

See Chapter 7 for methods on EdU application.

EdU detection

See Chapter 3 for methods on EdU detection.

CHAPTER 9: CONCLUSION

Here I provide evidence that CREB activity in quiescent SCs directs Mpp7 expression, which in turn maintains the protein level and/or localization of known (Par-3 and YAP) and new (AMOT) SC regulators. Given CREB activity, as well as Mpp7 and AMOT expression extend into the period of myoblast activation, CREB-Mpp7-AMOT forms a previously uncharacterized regulatory axis that endows quiescent SCs with the competence to initiate expansion and maintain proliferative capacity of SC-derived myoblasts.

Muscle regeneration requires CREB activity

I found that pCREB displays dynamic changes during myogenic progression, extending previous reports for CREB activity in myogenic progenitors and myoblasts (Chen et al., 2005; Stewart et al., 2011). Although crushed muscle extracts and bFGF could stimulate pCREB in myoblasts (Stewart et al., 2011), neither was included in our culture. High pCREB levels in SCs and myoblasts are thus induced by myofibers, serum factors, or cell-cell paracrine signals. As all three CREB members are expressed in the SC lineage (Figure 42) they likely all contribute to the pCREB signal of SCs and myoblasts (Figure 1,3,4).

Instead of inactivating the combined 6 alleles of this gene family, I used A-CREB to selectively inhibit their activity collectively (Ahn et al., 1998) in the SC and found that regeneration was severely compromised by CREB inhibition. My observation that CREB activity is required for SC proliferation and self-renewal extends the gain-of-function data that CREB-YP enhances myoblasts proliferation (Stewart et al., 2011). Additionally, the role of CREB in the SC and in a regeneration context had not previously been

studied. The requirement for CREB in the regeneration of myofibers (Figure 9,10) can be directly related to its role in proliferation. However the finding that CREB can direct self-renewal was a surprise. Not only did CREB affect the number of total Pax7⁺ cells, which could represent both Pax7⁺ progenitor and self-renewing population, CREB maintains the ability to selectively enhance Pax7⁺/MyoD⁻ self-renewing cells (Figure 12, 18). This is the first time CREB has been shown to direct SC cell fate.

Mpp7 mediates CREB activity

Using a comparative RNA-seq approach, I identified Mpp7 as a downstream target of CREB in SCs (Figure 23). This provided initial evidence that Mpp7 was mediating the effects of CREB inhibition. I validated this hypothesis by performing rescue experiments whereby re-expressing Mpp7 alone is sufficient to restore the ability of SC_{SA-CREB} to proliferate and self-renew (Figure 27). Ectopic Mpp7 in control cells increases self-renewed SCs, but does not force myogenic expansion (Figure 27). One possibility is that the Mpp7-directed pathway is sufficient to drive self-renewal but it needs cooperation with additional signaling inputs for extra proliferative cycles and those inputs are limiting in culture. For example, HGF and FGF signaling are well known pathways for SC proliferation. Further exploration of the intersection and cooperation between Mpp7 and other SC proliferation regulators is needed.

CREB-Mpp7-AMOT axis endows quiescent SC the competence for expansion

Notably, the CREB-Mpp7-AMOT regulatory axis is established in quiescent SCs, while its inhibition seems to not affect Pax7 expression (Figure 6) or niche retention (Figure 7). Loss of Par-3, an apical determinant, likely causes the loss of apical restriction of M-cadherin/ β -catenin. Knockdown of Par3 in myofiber-associated myoblasts results in

fewer proliferative myoblasts and fewer differentiated cells *in vitro* (Troy et al., 2012), This is in correspondence with the lack of proliferation in Mpp7 knockdowns, however they differ in that shPar-3 promotes the Pax7⁺ cell fate (Troy et al., 2012) whereas Mpp7 knockdown promotes differentiation. Notably, because of the time for isolation and expression of shRNA, the nature of Par-3 loss during quiescence is unclear and should not be compared to Mpp7 loss in the SC_{SA-CREB} model. As M-cadherin and β -catenin have not been shown to be important for SC quiescence, their loss or changes may indeed have little impact on quiescent SC_{SA-CREB}. In summary, the loss of Mpp7 in the SC differs from studies identifying quiescence molecules, and instead provides evidence for an apical polarity regulator that allows for and maintains proliferation after activation.

More intriguing is the CREB-Mpp7-AMOT axis for regulation of YAP in quiescent SCs. YAP is detected in the nucleus of quiescent SCs, however YAP-directed proliferation is not operational (Figure 7,37). Recent studies have established an alternative concept that retention of quiescence relies on the active suppression of activation rather than passive preservation. Through the activity of microRNAs, chromatin modifiers and cell surface receptors SCs preserve a mitotically inactive state (Boonsanay et al., 2016; Cheung et al., 2012; Crist et al., 2012; Yamaguchi et al., 2015). SC_{SA-CREB} show defects in the apical domain during quiescence, however SC_{SA-CREB} exhibits a distinct phenotype from these SCs with inactivated quiescence program. SC_{SA-CREB} show no mitotic activity nor differentiation during quiescence and maintain Pax7 expression and position in the SC niche (Figure 7). SC_{SA-CREB} manifests myogenic defects only after injury and isolation.

Given that YAP localizes to the SC nucleus during quiescence while its downstream targets are not significantly downregulated upon A-CREB expression (Table 2), YAP must be prevented from action. I envision that YAP or its DNA binding co-factors TEAD1 and TEAD3, the only family members of the TEAD family expressed during quiescence (Figure 42) are prevented from accessing their target genes by the quiescent facultative heterochromatin and/or from inhibitory co-factors. In either scenario, the CREB-Mpp7-AMOT axis promotes YAP nuclear entry, which primes SCs for activation upon injury stimulus and perpetuates proliferative potential during transit amplification of myoblasts.

Mpp7-AMOT complex acts as a molecular scaffold for Par-3 and YAP signaling

In epithelial cell lines, Mpp7 associates with Dlg1 or Crb3-Mpp5m the core adherence and tight junction signaling components, respectively, and regulates the function of tight junctions (Bohl et al., 2007; Stucke et al., 2007). Here I focused on a lesser-studied link between Mpp7 and AMOT. Proteomic analysis of AMOT binding partners revealed two complexes: one containing the core tight junction regulators Rich1, Crb3, PATJ, and Mpp5 (AMOT-tight junction complex), and the other, AMOT-L1, AMOT-L2, Mupp1, and Mpp7 (Mpp7-AMOT complex) (Wells et al., 2006). The same study established a physical association between AMOT and Par-3 and their role in maintenance of tight junctions, but the Mpp7-AMOT complex was not explored. In SC_{SA-CREB}, Mpp7, AMOT and Par-3 staining signals are greatly diminished (Figure 25,26,31). Because only *Mpp7*'s transcript level is reduced among them (Figure 23) the protein stability of AMOT and Par-3 appears to be Mpp7-dependent, or they are mutually inter-dependent.

All components of the Mpp7-AMOT complex, but not all of those in the AMOT-tight junction complex, are expressed in the quiescent SCs, (Figure 23, 36). AMOT, as well as AMOT-L1 and AMOT-L2, have been shown to bind YAP and its related protein TAZ (Chan et al., 2011; Zhao et al., 2011). Current models in cell culture systems position AMOT as a cytoplasmic and tight junction localized binding partner of YAP, which restricts its activity by retaining it from the nucleus (Chan et al., 2011; Wang et al., 2011; Zhao et al., 2011). However, AMOT has been proposed to act positively to regulate YAP activity *in vivo* (Yi et al., 2013). Interestingly, YAP/TAZ can act synergistically with Pax7 for enhancing induction of Pax3, Mitf, and Myf5 enhancer reporter constructs (Manderfield et al., 2014) suggesting AMOT-mediated YAP activity could be directly affecting the transcriptional activity of Pax7 to promote self-renewal of SCs. SCs_{SA-CREB} have concomitant loss of Mpp7, AMOT, and YAP levels. RNAi data indicate that Mpp7, AMOT, AMOT-L1 and AMOT-L2 all contribute to nuclear accumulation of YAP in myoblasts. Thus, the Mpp7-AMOT complex acts as a positive regulator of YAP for adult myogenic expansion. I propose that Mpp7-AMOT complex is an alternative scaffold for the conventional AMOT-tight junction signaling complex for YAP and acts in parallel yet coordinated fashion with Par-3 signaling to drive SC proliferation and self-renewal after activation.

CHAPTER 10: EXCERPT FROM: A SERIES OF CRE-ER(T2) DRIVERS FOR MANIPULATION OF THE SKELETAL MUSCLE LINEAGE

The following text and accompanying figure were published in:
Southard, S., Low, S., Li, L., Rozo, M., Harvey, T., Fan, C.-M. and Lepper, C. (2014), A
series of Cre-ER^{T2} drivers for manipulation of the skeletal muscle lineage. *Genesis*,
52: 759–770. doi: 10.1002/dvg.22792

Reprinted with permission from John Wiley and Sons, license number: 3847701006631.

For the *Myod1*^{CE} allele, we did not observe cell marking by tmx at E8.75, but found cell marking in the lateral edge of inter-limb somites when tmx was administered at E9.75 (Fig. 3A). Given the perdurance of tmx of ~ 12 h in vivo (Nakamura *et al.*, 2006), this period overlaps with the earliest *Myod1* expression timing and pattern (Sassoon *et al.*, 1989). Progressively more facial and distal limb muscles were labeled at later stages (Fig. 3B-F). Eight to sixteen hours long X-gal reactions were needed to observe signals in these *Myod1*^{CE} embryos, likely reflecting that *Myod1*^{CE} marks mostly differentiating muscle cells that did not expand. Alternatively, lower levels of CE may be produced by *Myod1*^{CE} compared to *Pax3*^{CE}. The E13.75 to E15.25 treated embryos appeared to have less intense staining, likely due to lower substrate penetrance through the skin (Fig. 3E). Removal of skin from E14.75 to E16.25 treated embryos indeed increased staining signal (Fig. 3F). As E10.75 represents a time of robust labeling, we chose this time point for a longer term tracing to E16.25. These embryos showed staining of the trunk and body wall muscles as well as subcutaneous muscles (Fig. 3G). Although both fore and hind limb muscles were positive, the fore limb muscles showed a stronger staining, consistent with the more advanced developmental stage at E10.75 (the labeling time). The observation of strong staining after a 6-day chase suggests that minimally a fraction of myogenic progenitors at E10.75 were labeled by tamoxifen in the *Myod1*^{CE} embryos and subsequently amplified; thus, resulting in an expanded population of lineage-marked myogenic cells (in comparison to other *CE* alleles that did not display such a persistence, see below). This observation is consistent with the report that *Myod1*^{Cre} (constitutive *Cre* KI at the *Myod1* locus) directs lineage marking of muscle stem cells (Kanisicak *et al.*, 2009). For adult muscles, we selected the cardiac and various hind limb muscles for

whole mount analyses. Although there was no staining of the heart (Fig. 3I), differential staining in different muscle groups was obvious, with the soleus (Fig. 3L) showing the lowest staining signal among gastrocnemius, plantaris, TA, and Extensor Digitorum Longus (EDL) muscles (Fig. 3J,K,M,N). Differential *Myod1* expression levels among adult limb muscles and fiber types have indeed been reported (Hughes *et al.*, 1993, 1997). Cross section of the TA muscles showed a mosaic pattern of labeling intensity (Fig. 3O), likely reflecting differential levels of CE and/or frequency of reporter recombination in different myofibers.

Myod1^{CE};R26R^{LacZ}

Myod1^{CE} characterization. Time of tmx administration and embryo harvest is as in Figure 2. (A–F) Embryos (sagittal view) were subjected to X-gal reactions (8–16 h); insets are control embryos; embryo in (F) was skinned. (G) Transverse section of the embryo at the brachial level, and (H) fore limb (FL, left) and hind limb (HL, right) levels (24 h reaction); sc, spinal cord; s, scapula; h, humerus; u, ulna; f, femur. (I–N) Adult muscles subjected to whole mount X-gal reactions (overnight); muscle names at bottom. Corresponding muscles from animals without tmx treatment (inset in J, and left muscles in K–M) were photographed side by side. (O) Cross section of TA muscles stained for X-gal (overnight) and Nuclear Fast Red. Open stars, facial muscles; arrows, limb muscles, white arrows, trunk muscles. Scale bars = 500 μ m, except for in (O), 100 μ m.

**CHAPTER 11: EXCERPT FROM: MAKING SKELETAL MUSCLE FROM
PROGENITOR AND STEM CELLS: DEVELOPMENT VERSUS
REGENERATION**

The following was published in:

Fan, C.-M., Li, L., Rozo, M. E., & Lepper, C. (2012). Making Skeletal Muscle from Progenitor and Stem Cells: Development versus Regeneration. *Wiley Interdisciplinary Reviews. Developmental Biology*, 1(3), 315–327.

Reprinted with permission from John Wiley and Sons, license number: 3847701317920.

Myogenic induction by Wnt proteins

In the embryo, the spinal cord and surface ectoderm surrounding the somite are necessary and sufficient for inducing myogenesis^{17,61-63}. Several *Wnt* genes are expressed in these two tissues. Co-cultures of presomitic cells and cells producing selective Wnt proteins induce expression of *Pax3* and *Pax7*⁶⁴, as well as *Myf5* and *MyoD*^{65,66}. In accordance, *Wnt1;Wnt3a* (both normally expressed in the dorsal spinal cord) double mutant embryos have reduced expression of *Pax3* and *Myf5* in the medial dermomyotome⁶⁷. The myogenic inducing potential of Wnt genes expressed by the surface ectoderm has not been tested genetically. *In vitro* pharmacological studies suggest that Wnts activate the Gα - adenylyl cyclase - protein kinase A signaling cascade to phosphorylate the transcription factor CREB, which in turn activates myogenic genes. Consistently, both germ line inactivation of *Creb* and dominant negative *Creb* over-expression in the somite lead to severely reduced expression of *Pax3*, *Myf5*, and *MyoD in vivo*⁶⁶. In addition, the PKC pathway, which can be activated via Gα signaling, has also been implicated in myogenic induction by modulating *Pax3* activity and *MyoD* expression⁶⁸.

The canonical Wnt/β-catenin pathway also plays a role in myogenesis. Inactivation of *β-catenin* in presomitic mesoderm cells leads to disorganized somites due to segmentation defects⁶⁹, disallowing a firm conclusion about its role in the primary wave of myogenesis⁷⁰. *En1-Cre* directed *β-catenin* inactivation in the central dermomyotome leads to an increase in the domain of myogenic cells at the expense of dermal cells, indicating an inhibitory role of *β-catenin* during the secondary wave of myogenesis¹¹. By contrast, *β-catenin* inactivation by *Pax7-Cre* caused only a modest defect in muscle architecture, represented by a change in muscle fiber sub-type

distribution⁷⁰. Since both *Pax7* and *En1* are expressed in the central dermoymtome, the discrepancies likely reflect different timing of expression and/or efficiency of Cre between the two alleles. Analysis of the role of β -catenin via gene inactivation is further complicated by an accompanying cell adhesion defect in mutant cells. Inactivation of *BCL9*, which regulates β -catenin's nuclear activity but not its adhesion function, should in principle eliminate this issue. Yet, conditional inactivation of *BCL9* by *Myf5-Cre*, causes no developmental defects⁷¹. The timing of *Myf5-Cre* activity and BCL9 protein perdurance may obscure a potential role of the canonical pathway in embryonic myogenesis.

The role of Wnt signaling in adult regenerative myogenesis is multifaceted (Fig. 3). A selective combination of Wnt5a, 5b, 7a, and 7b can convert muscle resident CD45⁺Sca1⁺ cells (i.e. the side-population cells) to express Pax7⁷², suggesting that CD45⁺Sca1⁺ cells are a source of *de novo* Pax7⁺ stem cells for muscle regeneration. Although these *Wnt* genes were originally reported to be up-regulated during regeneration⁷², subsequent re-evaluation did not substantiate such claim⁷³. Thus, the physiological significance of the side-population cells and whether their conversion to Pax7⁺ cells occurs *in vivo* are not yet known. On the other hand, FGF6 and FGFR4 are expressed during the early phase of the regenerative response^{73,74}, and both *Fgf6* and *Fgfr4* mutants display compromised muscle regeneration^{74,75}, supporting the importance of FGF signaling pathway for proficient muscle repair.

For symmetric division of Pax7⁺ muscle stem cells, Wnt7a has been shown to employ the planar cell polarity (PCP) pathway: *Wnt7a* gene delivery into muscles via electroporation causes increased muscle stem cell number, and consequently muscle

hypertrophy, and the PCP component Vangl-2 is a likely effector mediating this function⁷⁶. Although β -catenin nuclear localization has been documented in cultured proliferating myoblasts, it may act in the transit amplifying progenitors rather than in the self-renewing stem cells⁷⁷. β -catenin nuclear localization is also detected in differentiating myogenic cells⁷¹. Importantly, *BCL9* inactivation or pharmacological intervention of β -catenin activity *in vivo* caused delayed myogenic differentiation but did not disturb progenitor proliferation during regeneration, evidence that the canonical pathway participates in the differentiation step^{71,78}. Wnt3a has also been shown to employ the canonical pathway to accelerate myocyte fusion using the *in vitro* C2C12 myoblast model⁷⁹. As myocyte fusion immediately follows differentiation, separating Wnt/ β -catenin functions in these two steps in unsynchronized populations of cells may prove to be difficult.

Lastly, Wnt/ β -catenin pathway activation also induces muscle fibrosis and thus, is implicated in the decline of muscle function in aging. Gene delivery of *Wnt3a* via intramuscular electroporation leads to fibrotic accumulation⁷⁶. *In vitro*, recombinant Wnt3a causes direct conversion of myoblasts into fibroblasts⁷⁸. Importantly, a β -catenin transcriptional reporter is activated in aging but not in young muscles after injury, and depletion of Wnt proteins via soluble Frz receptors can rejuvenize aged myoblasts to prevent fibrogenesis⁷¹. While Wnt acts locally to divert aging muscle stem cells to the fibrogenic fate, TGF β 1 has been reported to be a candidate systemic factor that may attenuate muscle stem cell activation^{80,81} as serum levels of TGF β 1 increase in aging humans and mice⁸². Most of the above cited effects of Wnt and TGF β 1 in adult and aging

muscle regeneration are primarily based on *in vitro* culture or *in vivo overexpression*, pharmacology and RNAi studies; the genetic evidence remains to be obtained.

Weissman, I.L. (2000). Stem cells: units of development, units of regeneration, and units in evolution. *Cell* 100, 157–168.

Wells, C.D., Fawcett, J.P., Traweger, A., Yamanaka, Y., Goudreault, M., Elder, K., Kulkarni, S., Gish, G., Virag, C., Lim, C., et al. (2006). A Rich1/Amot Complex Regulates the Cdc42 GTPase and Apical-Polarity Proteins in Epithelial Cells. *Cell* 125, 535–548.

Wen, Y., Bi, P., Liu, W., Asakura, A., Keller, C., and Kuang, S. (2012). Constitutive Notch activation upregulates Pax7 and promotes the self-renewal of skeletal muscle satellite cells. *Mol. Cell. Biol.* 32, 2300–2311.

Wright, W.E., Sassoon, D.A., and Lin, V.K. (1989). Myogenin, a factor regulating myogenesis, has a domain homologous to MyoD. *Cell* 56, 607–617.

Yaffe, D., and Feldman, M. (1965). THE FORMATION OF HYBRID MULTINUCLEATED MUSCLE FIBERS FROM MYOBLASTS OF DIFFERENT GENETIC ORIGIN. *Dev. Biol.* 11, 300–317.

Yamaguchi, M., Watanabe, Y., Ohtani, T., Uezumi, A., Mikami, N., Nakamura, M., Sato, T., Ikawa, M., Hoshino, M., Tsuchida, K., et al. (2015). Calcitonin Receptor Signaling Inhibits Muscle Stem Cells from Escaping the Quiescent State and the Niche. *Cell Rep.* 13, 302–314.

Yi, C., Shen, Z., Stemmer-Rachamimov, A., Dawany, N., Troutman, S., Showe, L.C., Liu, Q., Shimono, A., Sudol, M., Holmgren, L., et al. (2013). The p130 Isoform of Angiomotin Is Required for Yap-Mediated Hepatic Epithelial Cell Proliferation and Tumorigenesis. *Sci. Signal.* 6, ra77–ra77.

Zammit, P.S., Heslop, L., Hudon, V., Rosenblatt, J.D., Tajbakhsh, S., Buckingham, M.E., Beauchamp, J.R., and Partridge, T.A. (2002). Kinetics of myoblast proliferation show that resident satellite cells are competent to fully regenerate skeletal muscle fibers. *Exp. Cell Res.* 281, 39–49.

Zammit, P.S., Golding, J.P., Nagata, Y., Hudon, V., Partridge, T.A., and Beauchamp, J.R. (2004). Muscle satellite cells adopt divergent fates: a mechanism for self-renewal? *J. Cell Biol.* *166*, 347–357.

Zhang, X., Odom, D.T., Koo, S.-H., Conkright, M.D., Canettieri, G., Best, J., Chen, H., Jenner, R., Herbolsheimer, E., Jacobsen, E., et al. (2005). Genome-wide analysis of cAMP-response element binding protein occupancy, phosphorylation, and target gene activation in human tissues. *Proc. Natl. Acad. Sci. U. S. A.* *102*, 4459–4464.

Zhao, B., Li, L., Lu, Q., Wang, L.H., Liu, C.-Y., Lei, Q., and Guan, K.-L. (2011). Angiomotin is a novel Hippo pathway component that inhibits YAP oncoprotein. *Genes Dev.* *25*, 51–63.

CURRICULUM VITAE

3520 San Martin Dr.
Baltimore, MD 21218
Cell Phone: (510) 219-0743
Email: li@ciwemb.edu

Birth

September 22, 1981 in San Francisco, CA, U.S.A.

Education

Ph.D. Cell, Molecular, Developmental Biology, and Biophysics Department
Candidate Johns Hopkins University
 July 2009 to current

M.S. Biology Department
 San Francisco State University
 June 2009

B.S. Molecular and Cell Biology Department
 University of California, Berkeley
 December 2003

Teaching Experience

2014 Baltimore Polytechnic Institute, Course on PCR
2012 Baltimore Talent Development High School, Biology teaching session
2010 Graduate Teaching Assistant, Developmental Biology
2010 Graduate Teaching Assistant, Genetics
2007-2009 Graduate Teaching Associate, Introduction to Biology
2008 SEPAL, Expanding Your Horizons (EYH)

Appointments

2006-2007 Research Associate, United States Department of Agriculture, Albany, CA
2004-2006 Laboratory Assistant, United States Department of Agriculture, Albany, CA
2001-2004 Laboratory Assistant, University of California, Berkeley, Berkeley, CA

Publications

2014 Southard S, Low SH, Li L, Rozo M, Harvey T, Fan CM, Lepper C. A Series of Cre-ERT2 Drivers for Manipulation of the Skeletal Muscle Lineage. *Genesis*, Aug;52(8):759-70

2014 Galli L, Szabo LA, Li L, Htaik YM, Onguka O, Burrus LW. Concentration-dependent effects of WNTLESS on WNT1/3A signaling. *Developmental Dynamics*, 2014 Sep;243(9):1095-105

- 2014 Galli LM, Munji RN, Chapman SC, Easton A, Li L, Onguka O, Ramahi JS, Suriben R, Szabo LA, Teng C, Tran B, Hannoush RN, Burrus LW. Frizzled10 mediates WNT1 and WNT3A signaling in the dorsal spinal cord of the developing chick embryo. *Developmental Dynamics* 243(6):833-43.
- 2012 Fan CM, Li L, Rozo ME, Lepper C. Making skeletal muscle from progenitor and stem cells: development versus regeneration. *Wiley Interdisciplinary Reviews: Developmental Biology* (3):315-27
- 2005 Curry JD, Li L, Schlissel MS. Quantification of Jkappa signal end breaks in developing B cells by blunt-end linker ligation and qPCR. *Journal of Immunological Methods* 296(1-2):19-30.
- Awards
- 2008 Gloria Spencer Women's Association Scholarship
- 2008 Nelson Scholarship
- 2008 Maxwell Scholarship
- 2009 Graduate Student Project Showcase Award
